Notes on (algebra based) Physics

Prachi Parashar\textsuperscript{1} and K. V. Shajesh\textsuperscript{2}

Department of Physics,
Southern Illinois University–Carbondale,
Carbondale, Illinois 62901, USA.

Part I of the following document is under construction in Spring 2016. Part II was written in Fall 2015. It will be updated periodically, and will evolve during the semester. It is not a substitute for the assigned textbook for the course, but a supplement prepared as a study-guide.

Last updated: April 6, 2016

These are notes prepared for the benefit of students enrolled in PHYS-203A and PHYS-203B, algebra based introductory physics courses for non-physics majors, at Southern Illinois University–Carbondale. The following textbooks were extensively used in this compilation.

1. (Assigned Textbook in Fall 2015)
   Physics, Ninth Edition,
   John D. Cutnell and Kenneth W. Johnson,
   John Wiley & Sons, Inc.

2. Fundamentals of physics, Fifth Edition,
   David Halliday, Robert Resnick, and Jearl Walker,
   John Wiley & Sons, Inc.

3. (Assigned Textbook in Spring 2016)
   OpenStax College, College Physics,
   OpenStax College, 21 June 2012.

Part I

Mechanics
Chapter 1

Measurement

1.1 International System (SI) of units

Three of the total of seven SI base units are

<table>
<thead>
<tr>
<th>Physical Quantity</th>
<th>Dimension</th>
<th>Unit Name</th>
<th>Unit Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>Time</td>
<td>T</td>
<td>second</td>
<td>s</td>
</tr>
<tr>
<td>Length</td>
<td>L</td>
<td>meter</td>
<td>m</td>
</tr>
<tr>
<td>Mass</td>
<td>M</td>
<td>kilogram</td>
<td>kg</td>
</tr>
</tbody>
</table>

The remaining four physical quantities in the SI base units are: charge (measured in Coulomb), temperature (measured in Kelvin), amount of substance (measured in mole), and luminosity (measured in candela).

Orders of magnitude of physical quantities are written in powers of ten using the following prefixes:

\[
\begin{align*}
    c &= 10^{-2}, & m &= 10^{-3}, & \mu &= 10^{-6}, & n &= 10^{-9}, & p &= 10^{-12}, \\
    d &= 10^{2},  & k &= 10^{3},  & M &= 10^{6},  & G &= 10^{9},  & T &= 10^{12}.
\end{align*}
\]

Lecture-Example 1.1:
Why is the following situation impossible? A room measures 4.0 m × 4.0 m, and its ceiling is 3.0 m high. A person completely wallpapers the walls of the room with the pages of a book which has 1000 pages of text (on 500 sheets) measuring 0.21 m × 0.28 m. The person even covers the door and window.

1.2 Dimensional analysis

Addition and subtraction is performed on similar physical quantities. Consider the mathematical relation between distance \( x \), time \( t \), velocity \( v \), and acceleration \( a \), given by

\[
x = vt + \frac{1}{2}at^2.
\]

This implies that

\[
[x] = [vt] = [at^2] = L,
\]

where we used the notation involving the square brackets

\[
[a] = \text{dimension of the physical quantity represented by the symbol } a.
\]
| $10^{-35}$ m | Planck length |
| $10^{-18}$ m | size of electron |
| $10^{-15}$ m | size of proton |
| $10^{-10}$ m | size of atom |
| $10^{-8}$ m | size of a virus |
| $10^{-6}$ m | size of a bacteria |
| $10^{-6}$ m | size of a human |
| $10^0$ m | size of Earth |
| $10^{12}$ m | size of solar system |
| $10^{15}$ m | distance to closest star |
| $10^{21}$ m | size of a galaxy |
| $10^{24}$ m | distance to closest galaxy |
| $10^{25}$ m | size of observable universe |

Table 1.1: Orders of magnitude (length). See also a slideshow titled *Secret Worlds: The Universe Within*, which depicts the relative scale of the universe.

Mathematical functions, like logarithm and exponential, are evaluated on numbers, which are dimensionless.

**Lecture-Example 1.2:**
Consider the mathematical expression
\[ x = vt + \frac{1}{2!}at^2 + \frac{1}{3!}bt^3 + \frac{1}{4!}ct^4, \]  
(1.5)
where $x$ is measured in units of distance and $t$ is measured in units of time. Determine the dimension of the physical quantities represented by the symbols $v$, $a$, $b$, and $c$.

- Deduce $[x] = [vt]$. Thus, we have $[v] = LT^{-1}$.
- Deduce $[x] = [at^2]$. Thus, we have $[a] = LT^{-2}$.
- Deduce $[x] = [bt^3]$. Thus, we have $[b] = LT^{-3}$.
- Deduce $[x] = [ct^4]$. Thus, we have $[c] = LT^{-4}$.

**Lecture-Example 1.3:** (Wave equation)
Consider the mathematical expression, for a travelling wave,
\[ y = A \cos(kx - \omega t + \delta), \]  
(1.6)
where $x$ and $y$ are measured in units of distance, $t$ is measured in units of time, and $\delta$ is measured in units of angle (radians, that is dimensionless). Deduce the dimensions of the physical quantities represented by the symbols $A$, $k$, and $\omega$. Further, what can we conclude about the nature of physical quantity constructed by $\frac{\omega}{k}$?

- Deduce $[y] = [A]$. Thus, conclude $[A] = L$.
- Deduce $[kx] = [\delta] = 1$. Thus, conclude $[k] = L^{-1}$.
- Deduce $[\omega t] = [\delta] = 1$. Thus, conclude $[\omega] = T^{-1}$.
1.3. MEASUREMENT

- Deduce $[kx] = [\omega t]$. Thus, conclude that $[\frac{\omega}{k}] = LT^{-1}$. This suggests that the construction $\frac{\omega}{k}$ measures speed.

Lecture-Example 1.4: (Weyl expansion)
The list of overtones (frequencies of vibrations) of a drum is completely determined by the shape of the drum-head. Is the converse true? That is, what physical quantities regarding the shape of a drum can one infer, if the complete list of overtones is given. This is popularly stated as ‘Can one hear the shape of a drum?’ Weyl expansion, that addresses this question, is

$$E = \frac{A}{\delta^3} + \frac{C}{\delta^2} + \frac{B}{\delta} + a_0 + a_1 \delta + a_2 \delta^2 + \ldots,$$

(1.7)

where $E$ is measured in units of inverse length, and $\delta$ is measured in units of length. Deduce that the physical quantities $A$ and $C$ have the dimensions of area and circumference, respectively.

Lecture-Example 1.5:
What can you deduce about the physical quantity $c$ in the famous equation

$$E = mc^2,$$

(1.8)

if the energy $E$ has the dimensions $ML^2T^{-2}$ and mass $m$ has the dimension $M$.

- $[c] = LT^{-1}$. Thus, the physical quantity $c$ has the dimension of speed.

1.3 Measurement

The measurement of a quantity $A$ is reported in the form

$$A \pm \delta A,$$

(1.9)

where $\delta A$ is the quantitative measure of the error (or the uncertainty) in the measurement of the quantity $A$. If the measurement involves a series of measurements, $A$ is reported as the average of these measurements and $\delta A$ is reported as the standard deviation of the measurements.

The error $\delta A$, by its very nature, typically has only one significant digit. This, in turn, decides the number of significant digits in the quantity $A$.

1.4 Homework problems

Homework-Problem 1.1: The speed limit on certain interstate highways is 70 miles per hour.

1. What is this in meter per second?

2. How many km/h is this?
Homework-Problems:

**Homework-ProBLEM 1.2:** Tectonic plates are large segments of the earth’s crust that move slowly. Suppose one such plate has an average speed of 2.0 cm per year.

1. What distance does it move in 30 seconds at this speed?
2. What is its speed in miles per million years?

**Hints:** Speed is defined as

\[ \text{speed} = \frac{\text{distance}}{\text{time}}. \]  \hfill (1.10)

**Homework-ProBLEM 1.3:** Refer to the relevant table in textbook to determine the average distance between the Earth and the Sun. Then calculate the average speed of the Earth in its orbit in kilometers per second. What is this in meters per second?

**Hints:** Speed of an object moving in a circle is given by

\[ \text{speed} = \frac{\text{circumference}}{\text{time period}}. \]  \hfill (1.11)

**Homework-ProBLEM 1.4:** A car speedometer has a 5% uncertainty. What is the range of possible speeds when it reads 70 km/h? Convert this to miles per hour.

**Hints:** Let \( A = 70 \text{ km/h} \). We are given that \( \delta A = 0.05 A \). The problem requires us to calculate \( A + \delta A \) and \( A - \delta A \).
Chapter 2

Motion in one dimension

2.1 Motion

The pursuit of science is to gain a fundamental understanding of the principles governing our nature. A fundamental understanding includes the ability to make predictions.

Time

The very idea of prediction stems from the fact that time $t$ always moves forward, that is,

$$\Delta t = t_f - t_i > 0,$$

where $t_i$ is an initial time and $t_f$ represents a time in the future. We will often choose the initial time $t_i = 0$.

Position

Our immediate interest would be to predict the position of an object. The position of an object (in space), relative to another point, is unambiguously specified as $x$. The position is a function of time, that is, $x(t)$. Newtonian mechanics, the subject of discussion, proposes a strategy to determine the function $x(t)$, thus offering to predict the position of the object in a future time. This sort of prediction is exemplified every time a spacecraft is sent out, because we predict that it will be at a specific point in space at a specific time in the future. We will mostly be interested in the change in position,

$$\Delta x = x_f - x_i.$$

Velocity

The instantaneous velocity of an object at time $t$ is defined as the ratio of the change in position and change in time, which is unambiguous in the instantaneous limit $\Delta t \to 0$,

$$v = \frac{\Delta x}{\Delta t}.$$

The magnitude of the instantaneous velocity vector is defined as the speed.

The average velocity, defined as the average of the instantaneous velocity over time, can be shown (using calculus) to be given by

$$v_{\text{avg}} = \frac{x_f - x_i}{t_f - t_i}.$$
This average velocity, in Eq. (2.4), is used in non-calculus-based discussions in place of the instantaneous velocity, which has its limitations, but is nevertheless sufficient for a requisite understanding. In this context the speed is often also associated with the magnitude of the average velocity.

Lecture-Example 2.1: (Case $t_1 = t_2$)
While travelling in a straight line a car travels the first segment of distance $d_1$ in time $t_1$ at an average velocity $v_1$, and it travels the second segment of distance $d_2$ in time $t_2 = t_1$ at an average velocity $v_2$. Show that the velocity of the total trip is given by the average of the individual velocities,

$$v_{tot} = \frac{v_1 + v_2}{2}.$$  \hfill (2.5)

Lecture-Example 2.2: (Case $d_1 = d_2$)
While travelling in a straight line a car travels the first segment of distance $d_1$ in time $t_1$ at an average velocity $v_1$, and it travels the second segment of distance $d_2 = d_1$ in time $t_2$ at an average velocity $v_2$. Show that inverse of the velocity of the total trip is given by the average of the inverse of the individual velocities,

$$\frac{2}{v_{tot}} = \frac{1}{v_1} + \frac{1}{v_2}.$$  \hfill (2.6)

- Consider the following related example. You travel the first half segment of a trip at an average velocity of 50 miles/hour. What is the average velocity you should maintain during the second segment, of equal distance, to login an average velocity of 60 miles/hour for the total trip? Repeat for the case when you travel the first segment at 45 miles/hour.

- Next, repeat for the case when you travel the first segment at 30 miles/hour. Comprehend this. (Hint: Assume the total distance to be 60 miles and calculate the time remaining for the second segment.)

Acceleration

The acceleration of an object at time $t$ is defined as the rate of change in velocity, which is unambiguous in the instantaneous limit $\Delta t \to 0$,

$$a = \frac{\Delta v}{\Delta t}.$$  \hfill (2.7)

2.2 Graphical analysis

Position-time graph

In the position-time graph the slope of the tangent to the position curve at a certain time represents the instantaneous velocity. The inverse of the curvature of the position curve at a certain time is related to the instantaneous acceleration.

Velocity-time graph

In the velocity-time graph the slope of the tangent to the velocity curve at a certain time represents the instantaneous acceleration. The area under the velocity curve is the position up to a constant.
2.3 MOTION WITH CONSTANT ACCELERATION

2.3 Motion with constant acceleration

Definition of velocity and acceleration supplies the two independent equations for the case of constant acceleration:

\[
\frac{\Delta x}{\Delta t} = \frac{v_f + v_i}{2}, \quad (2.8a)
\]

\[
a = \frac{v_f - v_i}{\Delta t}. \quad (2.8b)
\]

It is worth emphasizing that the relation in Eq. \((2.8a)\) is valid only for the case of constant velocity. It is obtained by realizing that velocity is a linear function of time for constant acceleration in Eq. \((2.4)\). Eqs. \((2.8a)\) and \((2.8b)\) are two independent equations involving five independent variables: \(\Delta t, \Delta x, v_i, v_f, a\). We can further deduce,

\[
\Delta x = v_i \Delta t + \frac{1}{2} a \Delta t^2, \quad (2.8c)
\]

\[
\Delta x = v_f \Delta t - \frac{1}{2} a \Delta t^2; \quad (2.8d)
\]

\[
v_f^2 = v_i^2 + 2a\Delta x, \quad (2.8e)
\]

obtained by subtracting, adding, and multiplying, Eqs. \((2.8a)\) and \((2.8b)\), respectively. There is one of the five variables missing in each of the Eqs. \((2.8)\), and it is usually the variable missing in the discussion in a particular context.

Lecture-Example 2.3: While driving on a highway you press on the gas pedals for 20.0 seconds to increase your speed from an initial speed of 40.0 miles/hour to a final final speed of 70.0 miles/hour. Assuming uniform acceleration find the acceleration. (Answer: \(0.89 \text{ m/s}^2\).)

To gain an intuitive feel for the magnitude of the velocities it is convenient to observe that, (using 1 mile \(\sim\) 1609 m.)

\[
\frac{2 \text{ miles}}{\text{hour}} = \frac{1 \text{ m}}{\text{s}}, \quad (2.9)
\]
1 m/s  human walking speed
10 – 50 m/s  typical speed on a highway
340 m/s  speed of sound, speed of a typical fighter jet
1000 m/s  speed of a bullet
11 200 m/s  minimum speed necessary to escape Earth’s gravity
299 792 458 m/s  speed of light

Table 2.1: Orders of magnitude (speed)

1 m/s²  typical acceleration on a highway
$g = 9.8 \text{ m/s}^2$  acceleration due to gravity on surface of Earth
3g  space shuttle launch
5g  causes dizziness (and fear) in humans
6g  high-g roller coasters and dragsters
8g  fighter jets pulling out of a dive
20g  damage to capillaries
50g  causes death, a typical car crash

Table 2.2: Orders of magnitude (acceleration)
correct to one significant digit, which is more accurately 1 miles/hour = 0.447 m/s.

Lecture-Example 2.4:
While standing on a $h = 50.0 \text{ m}$ tall building you throw a stone straight upwards at a speed of $v_i = 15 \text{ m/s}$.

- How long does the stone take to reach the ground. (Be careful with the relative signs for the variables.) Mathematically this leads to two solution. Interpret the negative solution.

- How high above the building does the stone reach?

- What is the velocity of the stone right before it reaches the ground?

- How will your results differ if the stone was thrown vertically downward with the same speed?

Lecture-Example 2.5:
The kinematic equations are independent of mass. Thus, the time taken to fall a certain distance is independent of mass. The following BBC video captures the motion of a feather and a bowling ball when dropped together inside the world’s biggest vacuum chamber.

https://www.youtube.com/watch?v=E43-CfukEgs

Lecture-Example 2.6:
A fish is dropped by a pelican that is rising steadily at a speed $v_i = 4.0 \text{ m/s}$. Determine the time taken for the fish to reach the water $15.0 \text{ m}$ below. How high above the water is the pelican when the fish reaches the water?
2.3. MOTION WITH CONSTANT ACCELERATION

- The distance the fish falls is given by, \( (x_f \text{ is chosen to be positive upward so that } v_i \text{ is positive when the fish is moving upward}) \)
  \[ x_f = v_i t - \frac{1}{2} g t^2, \tag{2.10} \]
  and the distance the pelican moves up in the same time is given by \( (x_p \text{ is chosen to be positive upward}) \)
  \[ x_p = v_i t. \tag{2.11} \]
  At the time the fish hits the water we have \( x_f = -15.0 \text{ m}. \) (Answer: \( t = 2.2 \text{ s or } -1.4 \text{ s}. \) Interpret the meaning of both solutions and chose the one appropriate to the context. Use this time to calculate \( x_p = 8.8 \text{ m}, \) which should be added to 15.0 m to determine how high above the water pelican is at this time.)

- Repeat for the case when the pelican is descending at a speed \( v_i. \) Compare the answers for the times with the negative solution in the rising case. (Answer: \( t = 1.4 \text{ s or } -2.2 \text{ s}. \) Use this time to calculate \( x_p = -5.6 \text{ m}.) \)

Lecture-Example 2.7: (Speeder and cop)
A speeding car is moving at a constant speed of \( v = 80.0 \text{ miles/hour} \) (35.8 m/s). A police car is initially at rest. As soon as the speeder crosses the police car the cop starts chasing the speeder at a constant acceleration of \( a = 2.0 \text{ m/s}^2. \) Determine the time it takes for the cop to catch up with the speeder. Determine the distance travelled by the cop in this time.

- The distance travelled by the cop is given by
  \[ x_c = \frac{1}{2} a t^2, \tag{2.12} \]
  and the distance travelled by the speeder is given by
  \[ x_s = vt. \tag{2.13} \]
  When the cop catches up with the speeder we have
  \[ x_s = x_c. \tag{2.14} \]

- How would your answers change if the cop started the chase \( t_0 = 1 \text{ s} \) after the speeder crossed the cop? This leads to two mathematically feasible solutions, interpret the unphysical solution. Plot the position of the speeder and the cop on the same position-time plot.

Lecture-Example 2.8:
A key falls from a bridge that is 50.0 m above the water. It falls directly into a boat that is moving with constant velocity \( v_b, \) that was 10.0 m from the point of impact when the key was released. What is the speed \( v_b \) of the boat?

- The distance the key falls is given by
  \[ d_k = \frac{1}{2} g t^2, \tag{2.15} \]
  and the distance the boat moves in the same time is given by
  \[ d_b = v_b t. \tag{2.16} \]
  Eliminating \( t \) gives a suitable equation.
Lecture-Example 2.9: (Drowsy cat)
A drowsy cat spots a flowerpot that sails first up and then down past an open window. The pot is in view for a total of 0.50 s, and the top-to-bottom height of the window is 2.00 m. How high above the window top does the flower pot go?

- The time taken to cross the window during the upward motion is the same as the time taken during the downward motion. Determine the velocity of the flowerpot as it crosses the top edge of the window, then using this information find the answer. (Answer: 2.34 m.)

Lecture-Example 2.10:
A man drops a rock into a well. The man hears the sound of the splash $T = 2.40$ s after he releases the rock from rest. The speed of sound in air (at the ambient temperature) is $v_0 = 336$ m/s. How far below the top of the well $h$ is the surface of the water? If the travel time for the sound is ignored, what percentage error is introduced when the depth of the well is calculated?

- The time taken for the rock to reach the surface of water is
  \[ t_1 = \frac{2h}{g}, \tag{2.17} \]
  and the time taken for the sound to reach the man is given by
  \[ t_2 = \frac{h}{v_0}, \tag{2.18} \]
  and it is given that
  \[ t_1 + t_2 = T. \tag{2.19} \]
  This leads to a quadratic equation in $h$ which has the solutions
  \[ h = \frac{v_0^2}{g} \left[ 1 + \frac{gT}{v_0} \right] \pm \sqrt{\left( 1 + \frac{gT}{v_0} \right)^2 - 2 \frac{gT}{v_0}}. \tag{2.20} \]
  Travel time for the sound being ignored corresponds to the limit $v_0 \to \infty$. The parameter $gT/v_0 \sim 0.07$ tells us that this limit will correspond to an error of about 7%.

- The correct solution corresponds to the one from the negative sign, $h = 26.4$ m. The other solution, $h = 24630$ m, corresponds to the case where the rock hits the surface of water in negative time, which is of course unphysical in our context. Visualize this by plotting the path of the rock as a parabola, which is intersected by the path of sound at two points.

Lecture-Example 2.11: (An imaginary tale: The story of $\sqrt{-1}$, by Paul J. Nahin)
Imagine that a man is running at his top speed $v$ to catch a bus that is stopped at a traffic light. When he is still a distance $d$ from the bus, the light changes and the bus starts to move away from the running man with a constant acceleration $a$.

- When will the man catch the bus?
- What is the minimum speed necessary for the man to catch the bus?
- If we suppose that the man does not catch the bus, at what time is the man closest to the bus?
Chapter 3

Vector algebra

3.1 Vector

The position of an object on a plane, relative to an origin, is uniquely specified by the Cartesian coordinates $(x, y)$, or the polar coordinates $(r; \theta)$. The position vector is mathematically expressed in the form

$$\mathbf{r} = x \mathbf{i} + y \mathbf{j},$$

where $\mathbf{i}$ and $\mathbf{j}$ are orthogonal unit vectors. The position vector is intuitively described in terms of its magnitude $r$ and direction $\theta$. These quantities are related to each other by the geometry of a right triangle,

$$r = \sqrt{x^2 + y^2}, \quad x = r \cos \theta, \quad \theta = \tan^{-1} \left( \frac{y}{x} \right), \quad y = r \sin \theta.$$  

A vector $\mathbf{A}$, representing some physical quantity other than the position vector, will be mathematically represented by

$$\mathbf{A} = A_x \mathbf{i} + A_y \mathbf{j},$$

whose magnitude will be represented by $|\mathbf{A}|$ and the direction by the angle $\theta_A$.

![Figure 3.1: The right triangle geometry of a vector $\mathbf{A}$.](image)

**Lecture-Example 3.1:**
Find the components of a vector $\mathbf{A}$ whose magnitude is 20.0 m and its direction is 30.0° counterclockwise with
respect to the positive x-axis.
Answer: $\hat{A} = (17.3\hat{i} + 10.0\hat{j}) \text{ m}.$

\textbf{Lecture-Example 3.2:} (Caution)
Inverse tangent is many valued. In particular,

$$\tan \theta = \tan(\pi + \theta).$$

(3.4)

This leads to the ambiguity that the vectors, $\vec{r} = x\hat{i} + y\hat{j}$ and $\vec{r} = -x\hat{i} - y\hat{j}$, produce the same direction $\theta$ using the formula $\tan^{-1}(y/x)$. This should be avoided by visually judging on the angles based on the quadrants the vector are in. Find the direction of the following two vectors:

\begin{align*}
\vec{A} &= 5.0\hat{i} + 10\hat{j}, \\
\vec{B} &= -5.0\hat{i} - 10\hat{j}.
\end{align*}

(3.5a) (3.5b)

We determine $\tan^{-1}(10/5) = \tan^{-1}(-10/-5) = 63^\circ$. Since the vector $\vec{A}$ is in the first quadrant we conclude that it makes $63^\circ$ counterclockwise w.r.t. $+x$ axis, and the vector $\vec{B}$ being in the third quadrant makes $63^\circ$ counterclockwise w.r.t. $-x$ axis or $243^\circ$ counterclockwise w.r.t. $+x$ axis.

\section{3.2 Addition and subtraction of vectors}

Consider two vectors $\vec{A}$ and $\vec{B}$ given by

\begin{align*}
\vec{A} &= A_x\hat{i} + A_y\hat{j}, \\
\vec{B} &= B_x\hat{i} + B_y\hat{j}.
\end{align*}

(3.6a) (3.6b)

The sum of the two vectors, say $\vec{C}$, is given by

$$\vec{C} = \vec{A} + \vec{B} = (A_x + B_x)\hat{i} + (A_y + B_y)\hat{j}.$$  

(3.7)

The difference of the two vectors, say $\vec{D}$, is given by

$$\vec{D} = \vec{A} - \vec{B} = (A_x - B_x)\hat{i} + (A_y - B_y)\hat{j}.$$  

(3.8)

It should be pointed out that the magnitudes and directions of a vector do not satisfy these simple rules. Thus, to add vectors, we express the vectors in their component form, perform the operations, and then revert back to the magnitude and direction of the resultant vector.

\textbf{Lecture-Example 3.3:} Given that vector $\vec{A}$ has magnitude $A = |\vec{A}| = 15\text{ m}$ and direction $\theta_A = 30.0^\circ$ counterclockwise w.r.t. $x$-axis, and that vector $\vec{B}$ has magnitude $B = |\vec{B}| = 20.0\text{ m}$ and direction $\theta_B = 45.0^\circ$ counterclockwise w.r.t. $x$-axis. Determine the magnitude and direction of the sum of the vectors.

- The given vectors are determined to be

\begin{align*}
\vec{A} &= 13\hat{i} + 7.5\hat{j}, \\
\vec{B} &= 14\hat{i} + 14\hat{j}.
\end{align*}

(3.9a) (3.9b)

We can show that

$$\vec{C} = \vec{A} + \vec{B} = (27\hat{i} + 22\hat{j}) \text{ m}.$$  

(3.10)
The magnitude of vector $\vec{C}$ is

$$C = |\vec{C}| = \sqrt{27^2 + 22^2} = 35 \text{ m},$$

and its direction $\theta_C$ counterclockwise w.r.t. $x$-axis is

$$\theta_C = \tan^{-1}\left(\frac{22}{27}\right) = 39^\circ.$$ (3.12)

### 3.3 Graphical method

Graphical method is based on the fact that the vector $\vec{A} + \vec{B}$ is diagonal of parallelogram formed by the vectors $\vec{A}$ and $\vec{B}$.

![Graphical method for vector addition and subtraction.](image)

Using the law of cosines,

$$C^2 = A^2 + B^2 - 2AB \cos \theta_{ab},$$

and the law of sines,

$$\frac{A}{\sin \theta_{bc}} = \frac{B}{\sin \theta_{ca}} = \frac{C}{\sin \theta_{ab}},$$

for a triangle, one determines the magnitude and direction of the sum of vectors.

**Lecture-Example 3.4:** (Caution)

Inverse sine function is many valued. In particular,

$$\sin \left(\frac{\pi}{2} - \theta\right) = \sin \left(\frac{\pi}{2} + \theta\right).$$ (3.15)

For example $\sin 85^\circ = \sin 95^\circ = 0.9962$. Consider the vector $\vec{A}$ with magnitude $|\vec{A}| = 1.0$ and direction $\theta_A = 0^\circ$ w.r.t. $+x$ axis, and another vector $\vec{B}$ with magnitude $|\vec{B}| = 2.5$ and direction $\theta_B = 60^\circ$ clockwise w.r.t. $-x$ axis. Using the law of cosines the magnitude of the vector $\vec{C} = \vec{A} + \vec{B}$ is determined as

$$C = \sqrt{1.0^2 + 2.5^2 - 2 \times 1.0 \times 2.5 \cos 60} = 2.18.$$ (3.16)

Next, using the law of sines we find

$$\frac{2.18}{\sin 60} = \frac{2.5}{\sin \theta_C} \quad \rightarrow \quad \sin \theta_C = 0.993 \quad \rightarrow \quad \theta_C = 83.2^\circ, 96.8^\circ.$$ (3.17)
Settle this confusion by evaluating the angle between the vectors $\vec{B}$ and $\vec{C}$, and thus determine $\theta_C = 96.8^\circ$.

---

**Lecture-Example 3.5: (One Two Three . . . Infinity, by George Gamow)**

“There was a young and adventurous man who found among his great-grandfather’s papers a piece of parchment that revealed the location of a hidden treasure. The instructions read: ‘Sail to __ North latitude and __ West longitude where thou wilt find a deserted island. There lieth a large meadow, not pent, on the north shore of the island where standeth a lonely oak and a lonely pine. There thou wilt see also an old gallows on which we once were wont to hang traitors. Start thou from the gallows and walk to the oak counting thy steps. At the oak thou must turn right by a right angle and take the same number of steps. Put here a spike in the ground. Now must thou return to the gallows and walk to the pine counting thy steps. At the pine thou must turn left by a right angle and see that thou takest the same number of steps, and put another spike in the ground. [Look] halfway between the spikes; the treasure is there.’

The instructions were quite clear and explicit, so our young man chartered a ship and sailed to the South Seas. He found the island, the field, the oak and the pine, but to his great sorrow the gallows was gone. Too long a time had passed since the document had been written; rain and sun and wind had disintegrated the wood and returned it to the soil, leaving no trace even of the place where it once had stood.

Our adventurous young man fell into despair, then in an angry frenzy began to [run] at random all over the field. But all his efforts were in vain; the island was too big! So he sailed back with empty hands. And the treasure is probably still there.”

Show that one does not need the position of the gallows to find the treasure.

- Let the positions be oak tree: $\vec{A}$, pine tree: $\vec{B}$, gallows: $\vec{G}$, spike A: $\vec{S}_A$, spike B: $\vec{S}_B$, treasure: $\vec{T}$. Choose the origin at the center of the line segment connecting the oak tree and pine tree. Thus we can write

  $$\vec{A} = -d\hat{i} + 0\hat{j}, \quad (3.18a)$$
  $$\vec{B} = d\hat{i} + 0\hat{j}. \quad (3.18b)$$

In terms of the unknown position of the gallows,

$$\vec{G} = x\hat{i} + y\hat{j}, \quad (3.19)$$

show that

$$\vec{S}_A = -(y + d)\hat{i} + (x + d)\hat{j}, \quad (3.20a)$$
$$\vec{S}_B = (y + d)\hat{i} - (x - d)\hat{j}. \quad (3.20b)$$

Thus, find the position of the treasure,

$$\vec{T} = \frac{1}{2}(\vec{S}_A + \vec{S}_B) = 0\hat{i} + d\hat{j}. \quad (3.21)$$
Chapter 4

Motion in two dimensions

4.1 Motion in 2D

Motion in each (orthogonal) direction is independently governed by the respective positions, velocities, and accelerations, with time being common to all dimensions that links them together. In terms of the position in each direction we can write the displacement vector as

\[ \Delta \vec{r} = \Delta x \hat{i} + \Delta y \hat{j}. \] (4.1)

The instantaneous velocity is defined as the rate of change of position, with the limit \( \Delta t \rightarrow 0 \) implicitly understood,

\[ \vec{v} = \frac{\Delta \vec{r}}{\Delta t} = v_x \hat{i} + v_y \hat{j}. \] (4.2)

The instantaneous acceleration is defined as the rate of change of velocity, with the limit \( \Delta t \rightarrow 0 \) implicitly understood,

\[ \vec{a} = \frac{\Delta \vec{v}}{\Delta t} = a_x \hat{i} + a_y \hat{j}. \] (4.3)

Lecture-Example 4.1:
A particle is moving in the \( xy \) plane. Its initial position, at time \( t = 0 \), is given by

\[ \vec{r}_0 = (2.0 \hat{i} + 3.0 \hat{j}) \text{ m}, \] (4.4)

and its initial velocity is given by

\[ \vec{v}_0 = (25 \hat{i} + 35 \hat{j}) \text{ m/s}. \] (4.5)

Find the position and velocity of the particle at time \( t = 15.0 \text{ s} \) if it moves with uniform acceleration

\[ \vec{a} = (-1.0 \hat{i} - 10.0 \hat{j}) \text{ m/s}^2. \] (4.6)

- The final position is determined using

\[ \vec{r} - \vec{r}_0 = \vec{v}_0 \Delta t + \frac{1}{2} \vec{a} \Delta t^2, \] (4.7)

and the final velocity is determined using

\[ \vec{v} = \vec{v}_0 + \vec{a} \Delta t. \] (4.8)
4.2 Projectile motion

Projectile motion is described by the uniform acceleration
\[ \vec{a} = 0 \hat{i} - g \hat{j}, \]  
(4.9)
where \( g = 9.80 \text{ m/s}^2 \) is the acceleration due to gravity.

**Lecture-Example 4.2: (Maximum height of a projectile)**

Show that the maximum height attained by a projectile is
\[ H = \frac{v_0^2 \sin^2 \theta_0}{2g}, \]  
(4.10)
where \( v_0 \) is the magnitude of the initial velocity and it is projected at an angle \( \theta_0 \).

**Lecture-Example 4.3: (Range of a projectile)**

Show that the range of a projectile is given by
\[ R = \frac{v_0^2 \sin 2\theta_0}{g}, \]  
(4.11)
where \( v_0 \) is the magnitude of the initial velocity and it is projected at an angle \( \theta_0 \).

- Show that the range of a projectile is a maximum when it is projected at 45° with respect to horizontal.
- The fastest sprint speed recorded for a human is 12.4 m/s, (updated in 2015 Sep). If a person were to jump off with this speed in a long jump event, at an angle 45° with respect to the horizontal, he/she would cover a distance of 15.7 m. Instead, if a person were to jump off with this speed at an angle 20° with respect to the horizontal, he/she would cover a distance of 10.1 m. The world record for long jump is about 9 m. Apparently, the technique used by professional jumpers does not allow them to jump at 45° without compromising on their speed, they typically jump at 20°. This seems to suggest that there is room for clever techniques to be developed in long jump.
- Cheetah is the fastest land animal, about 30 m/s. They cover about 7 m in each stride. Estimate the angle of takeoff for each stride, assuming a simple model. (Answer: 2°.)

**Lecture-Example 4.4: (Half a parabola)**

An airplane flying horizontally at a uniform speed of 40.0 m/s over level ground releases a bundle of food supplies. Ignore the effect of air on the bundle. The bundle is dropped from a height of 300.0 m.

- Observe that the initial vertical component of velocity of the bundle is zero, and the horizontal component of velocity remains constant.
- Determine the time taken for the drop. (Answer: 7.8 s.) Will this time change if the the airplane was moving faster or slower? Consider the extreme (unphysical) case when the airplane is horizontally at rest.
- Determine the horizontal distance covered by the bundle while it is in the air. (Answer: 313 m.)
- Determine the vertical and horizontal component of velocity just before it reaches the ground. (Answer: \( \vec{v}_f = (40.0 \hat{i} - 76 \hat{j}) \text{ m/s.} \)) Thus, determine the magnitude and direction of final velocity. (Answer: \( |\vec{v}_f| = 86 \text{ m/s}, \theta_f = 62^\circ \) below the horizontal.)
Lecture-Example 4.5: (Baseball)
A batter hits a ball with an initial velocity $v_i = 30.0 \text{ m/s}$ at an angle of $45^\circ$ above the horizontal. The ball is 1.2 m above the ground at the time of hit. There is 10.0 m high fence, which is a horizontal distance 100.0 m away from the batter.

- Determine the horizontal and vertical components of the initial velocity. (Answer: $\vec{v}_i = (21 \hat{i} + 21 \hat{j}) \text{ m/s}$.)
- Determine the horizontal range of the ball, ignoring the presence of the fence. (Answer: 92 m.)
- Determine the time the ball takes to traverse the horizontal distance to the fence. (Answer: 4.7 s.)
- Determine the vertical distance of the ball when it reaches the fence. (Answer: -9.1 m.) Thus, analyze whether the ball clears the fence.
- Repeat the above analysis for $v_i = 32 \text{ m/s}$. Does the ball clear the fence? What is the distance between the top of the fence and the center of the ball when the ball reaches the fence? (Answer: $y = 4.2 \text{ m}$, implying the ball hits 5.8 m below the top of fence.)
- Repeat the above analysis for $v_i = 33 \text{ m/s}$. Does the ball clear the fence? What is the distance between the top of the fence and the center of the ball when the ball reaches the fence? (Answer: $y = 1.0 \times 10^1 \text{ m}$, up to two significant digits, implying the ball is right at the top of the fence. We can not conclude if it clears the fence accurately, without having more precise information.)

Lecture-Example 4.6: (Galileo's thought experiment, from Dialogue Concerning the Two Chief World Systems, translated by Stillman Drake)
Hang up a bottle that empties drop by drop into a vessel beneath it. Place this setup in a ship (or vehicle) moving with uniform speed. Will the drops still be caught in the vessel? What if the ship is accelerating?

Lecture-Example 4.7: (Bullseye)
A bullet is fired horizontally with speed $v_i = 400.0 \text{ m/s}$ at the bullseye (from the same level). The bullseye is a horizontal distance $x = 100.0 \text{ m}$ away.

![Figure 4.1: Path of a bullet aimed at a bullseye.](image)

- Since the bullet will fall under gravity, it will miss the bullseye. By what vertical distance does the bullet miss the bullseye? (Answer: 31 cm.)
- At what angle above the horizontal should the bullet be fired to successfully hit the target? (Answer: $0.18^\circ$.)

Lecture-Example 4.8: (Simultaneously released target)
A bullet is aimed at a target (along the line). The target is released the instant the bullet is fired.
The path of the bullet is described by, using \( v_{iy} = v_0 \sin \theta_0 \),
\[
y_1 = v_0 \sin \theta_0 t - \frac{1}{2}gt^2,
\]
and the path of the target is described by
\[
y_2 = \frac{1}{2}gt^2.
\]
Adding the two equations we learn that, using \( H \sin \theta_0 = y_1 + y_2 \),
\[
H \sin \theta_0 = (y_1 + y_2) = v_0 \sin \theta_0 t_c.
\]
Thus, we learn that, there always exists a time \( t_c \) when the target and the bullet are at the same vertical position. Further, dividing the last equation with \( \tan \theta_0 \) we also learn that the bullet travels a horizontal distance \( H \cos \theta_0 \), with horizontal speed \( v_{ix} = v_0 \cos \theta_0 \), in the same time \( t_c \). Together, the implication is that the bullet hits the target independent of the initial conditions \( H \), \( v_0 \), and \( \theta_0 \). Observe that the time \( t_c \) is the time the bullet, moving with uniform speed \( v_0 \), would have taken to traverse the distance \( H \).

### 4.3 Galilean relativity

Let the relative positions of three particles \( A \), \( B \), and \( G \) be related by the relation
\[
\vec{r}_{BG} = \vec{r}_{BA} + \vec{r}_{AG}.
\]
See Fig. 4.3. Considering these to be the respective change in positions, dividing them by a change in time \( \Delta t \), and taking the instantaneous limit \( \Delta t \to 0 \), yields the relation between the respective relative velocities,
\[
\vec{v}_{BG} = \vec{v}_{BA} + \vec{v}_{AG}.
\]
Dividing by a change in time \( \Delta t \) again and taking the instantaneous limit \( \Delta t \to 0 \), yields the relativity of accelerations as measured by different observers,
\[
\vec{a}_{BG} = \vec{a}_{BA} + \vec{a}_{AG}.
\]

4.3. GALILEAN RELATIVITY

The speedometer of car $A$ measures its speed (with respect to ground) as $\vec{v}_{AG} = 70 \hat{i}$ miles/hour. The speedometer of car $B$ measures its speed (with respect to ground) as $\vec{v}_{BG} = 60 \hat{i}$ miles/hour. Determine the velocity of car $B$ with respect to car $A$.

- If the initial distance between the cars is 1.0 mile, (with car $A$ trailing car $B$,) determine the time (in minutes) it will take for car $A$ to overtake car $B$. (Answer: 6 min.)

Lecture-Example 4.10: (Moving walkway)
Two points inside an airport, separated by a distance of 100.0 m, are connected by a (straight) moving walkway $W$. The moving walkway has a velocity of $\vec{v}_{WG} = 3.0 \hat{i}$ m/s with respect to the ground $G$. A person $P$ walks on the moving walkway at a velocity of $\vec{v}_{PW} = 2.0 \hat{i}$ m/s with respect to the walkway. Determine the velocity of the person with respect to the ground $\vec{v}_{PG}$. (Answer: $5.0 \hat{i}$ m/s.)

- Compare the time taken for the person to walk the distance between the two points without using the walkway to that of using the walkway. (Answer: 50 s versus 20 s.)

- Consider a kid $P$ running on the walkway in the opposite direction with velocity $\vec{v}_{PW} = -4.0 \hat{i}$ m/s. Determine the velocity of the kid with respect to the ground $\vec{v}_{PG}$. (Answer: $-1.0 \hat{i}$ m/s.) If the kid starts from one end, determine the time taken for the kid to reach other end of the walkway. (Answer: 100 s.)

Lecture-Example 4.11: (Upstream versus downstream)
A river $R$ is flowing with respect to ground $G$ at a speed of $v_{RG} = 1.5$ m/s. A swimmer $S$ can swim in still water at $v_{SR} = 2.0$ m/s. Determine the time taken by the swimmer to swim a distance of 100.0 m downstream and then swim upstream the same distance, to complete a loop. (Answer: 229 s.)

Lecture-Example 4.12: (Boat crossing a river)
A river $R$ is flowing with respect to ground $G$ with velocity $\vec{v}_{RG} = 2.0 \hat{i}$ m/s. A boat $B$ can move in still water with a speed of $v_{BR} = 6.0$ m/s. The banks of the river are separated by a distance of 200.0 m.

- The boat is moving with respect to river with velocity $\vec{v}_{BR} = 6.0 \hat{j}$ m/s. The boat gets drifted. Determine the magnitude and direction of the velocity of the boat with respect to the river. (Answer: 6.3 m/s at an angle 18° clockwise with respect to $\hat{j}$.) How far down the river will the boat be drifted? (Answer: 67 m.)

- To reach the river right across, at what angle should the boat be directed? (Answer: 20° anticlockwise with respect to $\hat{j}$.) How much time does it take to reach the shore right across? (Answer: 35 s.)
Lecture-Example 4.13: (Rain)
A train $T$ travels due South at $30\,\text{m/s}$ relative to the ground $G$ in a rain $R$ that is blown toward the South by the wind. The path of each raindrop makes an angle of $70^\circ$ with the vertical, as measured by an observer stationary on the ground. An observer on the train, however, sees the drops fall perfectly vertically. Determine the speed of the raindrops relative to the ground.

Lecture-Example 4.14: (Navigation)
An aeroplane $A$ is flying at a speed of $75\,\text{m/s}$ with respect to wind $W$. The wind is flowing at a speed of $20\,\text{m/s}$ $30^\circ$ North of West with respect to ground $G$. In what direction should the aeroplane head to go due North?

- We have the relation
  \[ \vec{v}_{AG} = \vec{v}_{AW} + \vec{v}_{WG}, \]  
  where we are given
  \[ \vec{v}_{AG} = 0\hat{i} + v_{AG}\hat{j}, \]  
  \[ \vec{v}_{WG} = -20\cos30\hat{i} + 20\sin30\hat{j}, \]  
  \[ \vec{v}_{AW} = 75\cos\alpha\hat{i} + 75\sin\alpha\hat{j}. \]

This determines the direction to head as $\alpha = 77^\circ$ North of East. The resultant speed of the aeroplane due North is $83\,\text{m/s}$. 
Chapter 5

Newton’s laws of motion

5.1 Laws of motion

Without precisely defining them, we assume standard notions of force and mass.

Law of inertia: Newton’s first law of motion

The concept of inertia is the content of Newton’s first law of motion. It states that, a body will maintain constant velocity, unless the net force on the body is non-zero. It is also called the law of inertia. Velocity being a vector, constant here means constant magnitude and constant direction. In other words, a body will move along a straight line, unless acted upon by a force.

An inertial frame is a frame in which the law of inertia holds. A frame that is moving with constant speed with respect to the body is thus an inertial frame, but a frame that is accelerating with respect to the body is not an inertial frame. Einstein extended the law of inertia to non-Euclidean geometries, in which the concept of a straight line is generalized to a geodesic.

Newton’s second law of motion

The first law of motion states that a force causes a change in velocity of the body. In the second law the change in velocity is associated to the acceleration of the body. Newton’s second law of motion states that for a fixed force the acceleration is inversely proportional to the mass of the body. In this sense mass is often associated to the notion of inertia, because mass resists change in velocity. Newton’s second law of motion is expressed using the equation

\[ \vec{F}_1 + \vec{F}_2 + \cdots = m\vec{a}, \] (5.1)

where \( m \) is the mass of the body and \( \vec{a} \) is the acceleration of the body. The left hand side is the vector sum of the individual forces acting on the mass \( m \), which is often conveniently represented by \( \vec{F}_{\text{net}} \).

Newton’s third law of motion

A force is exerted by one mass on another mass. Newton’s third law states that the other mass exerts an equal and opposite reaction force on the first mass.

5.2 Force of gravity

Near to the surface of Earth a body of mass \( m \) experiences a force of gravity given by

\[ m\vec{g}, \] (5.2)
where $|\vec{g}| = 9.8 \text{ m/s}^2$ and the force $m\vec{g}$ is directed towards the center of Earth.

**Lecture-Example 5.1:**
A ball of mass 1.0 kg is dropped above the surface of Earth.

- Determine the magnitude and direction of the acceleration of the ball. (Answer: 9.8 m/s$^2$ towards the center of Earth.)
- According to Newton’s third law the Earth with a mass of $m_E = 5.97 \times 10^{24}$ kg also experiences the same force in the opposite direction. Determine the magnitude and direction of the acceleration of the Earth as a result. (Answer: $1.6 \times 10^{-24}$ m/s$^2$ towards the ball.)

### 5.3 Normal force

Due to the gravitational force acting on a body its tendency is to accelerate towards the center of Earth. This tendency is resisted when the body comes in contact with the surface of another body. The component of the force normal (perpendicular) to the plane of the surface is called the normal force, and is often represented by $\vec{N}$. Typical weighing scale, using a spring, measures the normal force, which is then divided by 9.8 m/s$^2$ to report the mass.

**Lecture-Example 5.2:** *(Normal force)*

A body of mass $m = 10.0$ kg rests on a weighing scale on a horizontal table.

- Determine the magnitude of the normal force acting on the mass. (Answer: 98 N.)
- Determine the magnitude of the normal force acting on the mass while you push on it vertically downwards with a force of 20 N. (Answer: 120 N.) Determine the reading on the scale. (Answer: 12 kg.)
- Determine the magnitude of the normal force acting on the mass while you pull on it vertically upwards with a force of 20 N. (Answer: 78 N.) Determine the reading on the scale. (Answer: 8.0 kg.)
- Determine the magnitude of the normal force acting on the mass while you pull on it vertically upwards with a force of 98 N. (Answer: 0 N.) Determine the reading on the scale. (Answer: 0 kg.)
- Determine the magnitude of the normal force acting on the mass while you pull on it vertically upwards with a force of 150 N. (Answer: 0 N.) Describe what happens. (Answer: The mass will accelerate upwards at 5.3 m/s$^2$.)

**Lecture-Example 5.3:** *(Elevator)*

Your mass is 75 kg. How much will you weigh on a bathroom scale (designed to measure the normal force in Newtons) inside an elevator that is

- at rest? (Answer: 740 N.)
- moving upward at constant speed? (Answer: 740 N.)
- moving downward at constant speed? (Answer: 740 N.)
- slowing down at 2.0 m/s$^2$ while moving upward? (Answer: 590 N.)
5.3. NORMAL FORCE

- speeding up at \(2.0 \text{ m/s}^2\) while moving upward? (Answer: \(890 \text{ N.}\))
- slowing down at \(2.0 \text{ m/s}^2\) while moving downward? (Answer: \(890 \text{ N.}\))
- speeding up at \(2.0 \text{ m/s}^2\) while moving downward? (Answer: \(590 \text{ N.}\))

**Lecture-Example 5.4:** (Frictionless incline)
A mass \(m\) is on a frictionless incline that makes an angle \(\theta\) with the horizontal. Let \(m = 25.0\text{ kg}\) and \(\theta = 30.0^\circ\).

![Figure 5.1: Lecture-Example 5.4](image)

- Using Newton’s law determine the equations of motion to be
  \[
  mg \sin \theta = ma, \quad (5.3a)
  \]
  \[
  N - mg \cos \theta = 0. \quad (5.3b)
  \]
- Determine the normal force. (Answer: \(N = 212 \text{ N.}\))
- Determine the acceleration of the mass. (Answer: \(a = 4.9 \text{ m/s}^2\).) How does the acceleration of the mass change if the mass is heavier or lighter?
- Starting from rest how long does the mass take to travel a distance of \(3.00\text{ m}\) along the incline? (Answer: \(1.1 \text{ s.}\))
- The optical illusion, The Demon Hill, by the artist Julian Hoeber, presumably motivated by naturally occurring ‘Mystery Spots’, are based on this idea. Check out this video:

  [https://www.youtube.com/watch?v=1BMSYXK4-AI](https://www.youtube.com/watch?v=1BMSYXK4-AI) (5:16 minutes)

**Lecture-Example 5.5:**
A mass \(m\) is pulled on a frictionless surface by a force \(\vec{F}_{\text{pull}}\) that makes an angle \(\theta\) with the horizontal. Let \(m = 25.0\text{ kg}, F_{\text{pull}} = 80.0 \text{ N}\), and \(\theta = 30.0^\circ\).

- Using Newton’s law determine the equations of motion to be
  \[
  F_{\text{pull}} \cos \theta = ma_x, \quad (5.4a)
  \]
  \[
  N + F_{\text{pull}} \sin \theta - mg = 0. \quad (5.4b)
  \]
• Determine the normal force. (Answer: $N = 205 \text{ N}$.)

• Determine the acceleration of the mass. (Answer: $a_x = 2.77 \text{ m/s}^2$.) Starting from rest how far does the mass move in one second?

• Discuss what happens if $\theta$ above the horizontal is increased.

• Discuss what happens if $\theta$ is below the horizontal.

**Lecture-Example 5.6:** (Three masses)
Three masses $m_1 = 10.0 \text{ kg}$, $m_2 = 20.0 \text{ kg}$, and $m_3 = 30.0 \text{ kg}$, are stacked together on a frictionless plane. A force $\vec{F}$ is exerted on $m_1$.

• Using Newton’s law determine the equations of motion to be

\begin{align}
F - C_{12} &= m_1 a, \\
N_1 &= m_1 g, \\
C_{21} - C_{23} &= m_2 a, \\
N_2 &= m_2 g, \\
C_{32} &= m_3 a, \\
N_3 &= m_3 g,
\end{align}

(5.5a)

\begin{align}
C_{12} &= C_{21}, \\
C_{21} &= C_{23}, \\
C_{32} &= C_{32}.
\end{align}

(5.5b)

Here $C_{ij}$ are contact forces acting on $i$ by $j$. Thus, determine the acceleration and contact forces to be

\begin{align}
a &= \frac{F}{(m_1 + m_2 + m_3)}, \\
C_{12} &= C_{21} = \frac{(m_2 + m_3)F}{(m_1 + m_2 + m_3)} = \frac{5}{6} F, \\
C_{23} &= C_{32} = \frac{m_3 F}{(m_1 + m_2 + m_3)} = \frac{1}{2} F.
\end{align}

(5.6a)

(5.6b)

(5.6c)
• Show that if the force $\vec{F}$ were exerted on mass $m_3$ instead we have

$$C_{12} = C_{21} = \frac{m_1 F}{(m_1 + m_2 + m_3)} = \frac{1}{6} F,$$  \hspace{1cm} (5.7a)

$$C_{23} = C_{32} = \frac{(m_1 + m_2) F}{(m_1 + m_2 + m_3)} = \frac{1}{2} F.$$  \hspace{1cm} (5.7b)

while the acceleration remains the same. Discuss the difference in the stresses on the surfaces of contact in the two cases.

5.4 Force due to tension in strings

Ropes and strings exert forces due to tension in them. In most of discussions we will assume the mass of the rope to be negligible in comparison to the masses of the moving bodies. That is we pretend the strings to be of zero mass.

Lecture-Example 5.7: (Double mass)

Two masses $m_1$ and $m_2$ are hanging from two ropes as described in Figure 5.4.

![Figure 5.4: Lecture-Example 5.7](image)

• Using Newton’s law determine the equations of motion to be

$$T_1 - T_2 = m_1 g,$$  \hspace{1cm} (5.8a)

$$T_2 = m_2 g.$$  \hspace{1cm} (5.8b)

Thus, show that

$$T_1 = (m_1 + m_2) g,$$  \hspace{1cm} (5.9a)

$$T_2 = m_2 g.$$  \hspace{1cm} (5.9b)

• Which rope has the larger tension in it? If the two ropes are identical, which rope will break first if the mass $m_2$ is gradually increased?

Lecture-Example 5.8: (Atwood’s machine)

The Atwood machine consists of two masses $m_1$ and $m_2$ connected by a massless (inextensible) string passing over a massless pulley. See Figure 5.5.
Massless pulley implies that $|\vec{T}_1| = |\vec{T}_2| = T$. And, inextensible string implies that $|\vec{a}_1| = |\vec{a}_2| = a$.

Using Newton’s law determine the equations of motion to be

\[
\begin{align*}
    m_2 g - T &= m_2 a, \quad (5.10a) \\
    T - m_1 g &= m_1 a. \quad (5.10b)
\end{align*}
\]

Thus, show that

\[
\begin{align*}
    a &= \left(\frac{m_2 - m_1}{m_2 + m_1}\right) g, \quad (5.11a) \\
    T &= \frac{2m_1 m_2 g}{(m_1 + m_2)}. \quad (5.11b)
\end{align*}
\]

Starting from rest how far do the masses move in a certain amount of time?

Determine the acceleration for $m_2 \gg m_1$ and describe the motion? Determine the acceleration for $m_2 \ll m_1$ and describe the motion? Plot $a$ as a function of $m_2$ for fixed $m_1$. 

Lecture-Example 5.9:
A mass is held above ground using two ropes as described in Figure 5.6. Let $m = 20.0 \, \text{kg}$, $\theta_1 = 30.0^\circ$, and $\theta_2 = 60.0^\circ$. 

\[
\begin{align*}
    T_2 \\
    \theta_2
\end{align*}
\]

Figure 5.6: Lecture-Example 5.9
• Using Newton’s law determine the equations of motion to be

\[ T_1 \sin \theta_1 + T_2 \sin \theta_2 = mg, \quad (5.12a) \]
\[ T_1 \cos \theta_1 - T_2 \cos \theta_2 = 0. \quad (5.12b) \]

Then, solve these equations to find

\[ T_1 = \frac{mg \cos \theta_2}{\sin(\theta_1 + \theta_2)}, \quad (5.13a) \]
\[ T_2 = \frac{mg \cos \theta_1}{\sin(\theta_1 + \theta_2)}. \quad (5.13b) \]

Which rope has the larger tension in it? If the two ropes are identical, which rope will break first if the mass is slowly increased?

• For the special case of \( \theta_1 + \theta_2 = \pi/2 \) verify that \( mg = \sqrt{T_1^2 + T_2^2} \).

**Lecture-Example 5.10:**
A mass \( m_2 = 2.0 \text{kg} \) is connected to another mass \( m_1 = 1.0 \text{kg} \) by a massless (inextensible) string passing over a massless pulley, as described in Figure 5.7. Surfaces are frictionless.

![Figure 5.7: Lecture-Example 5.10](image_url)

• Using Newton’s law determine the equations of motion to be

\[ m_2g - T = m_2a, \quad (5.14a) \]
\[ T = m_1a, \quad (5.14b) \]
\[ N_1 = m_1g. \quad (5.14c) \]

Thus, show that

\[ a = \frac{m_2g}{m_2 + m_1}, \quad (5.15a) \]
\[ T = \frac{m_1m_2g}{m_1 + m_2}, \quad (5.15b) \]
\[ N_1 = m_1g. \quad (5.15c) \]

• Starting from rest how far do the masses move in a certain amount of time?
• Determine the acceleration for $m_2 \gg m_1$ and describe the motion? Determine the acceleration for $m_2 \ll m_1$ and describe the motion? Plot $a$ as a function of $m_2$ for fixed $m_1$.

Lecture-Example 5.11: (Double incline)
A mass $m_2 = 2.0$ kg is connected to another mass $m_1 = 1.0$ kg by a massless (inextensible) string passing over a massless pulley, as described in Figure 5.8. Surfaces are frictionless.

![Figure 5.8: Lecture-Example 5.11](image)

• Using Newton’s law determine the equations of motion to be

$$m_1 g \sin \theta_1 - T = m_1 a, \quad N_1 = m_1 g \cos \theta_1, \quad (5.16a)$$

$$T - m_2 g \sin \theta_2 = m_2 a, \quad N_2 = m_2 g \cos \theta_2. \quad (5.16b)$$

Thus, show that

$$a = \frac{(m_1 \sin \theta_1 - m_2 \sin \theta_2)}{(m_1 + m_2)} g, \quad (5.17a)$$

$$T = \frac{m_1 m_2 (\sin \theta_1 + \sin \theta_2)}{(m_1 + m_2)} g. \quad (5.17b)$$

• Starting from rest how far do the masses move in a certain amount of time?

• Show that for $\theta_1 = \theta_2 = \pi/2$ the results for Atwood machine are reproduced.

• Show that the masses do not accelerate when $m_1 \sin \theta_1 = m_2 \sin \theta_2$. They accelerate to the right when $m_1 \sin \theta_1 > m_2 \sin \theta_2$, and they accelerate to the left when $m_1 \sin \theta_1 < m_2 \sin \theta_2$. 

Chapter 6

Frictional forces

6.1 Force of friction

While two solid surfaces are in contact, the force of friction is the force that resists the tendency of the surfaces to move relative to each other in the lateral direction (parallel to the surface). It acts in the direction opposite to the direction of tendency of motion.

We shall use an empirical model, by Coulomb, to model the force of friction. The Coulomb model assumes that the force of friction is independent of the apparent contact area between two surfaces. Instead it depends on the effective contact area between the two surfaces at the microscopic level. The effective contact area is typically less than the apparent contact area, but it could be more too. The Coulomb model assumes that the effective contact area is proportional to the normal force between the two surfaces. In particular, the Coulomb model states that

\[
F_f \begin{cases} \leq \mu_s N = F_{f,\text{max}}, & \text{(static case)} \\ = \mu_k N, & \text{(kinetic case)} \end{cases}
\]  

(6.1)

Lecture-Example 6.1:

A \( m = 20.0 \) kg \( (mg = 196 \) N) block is at rest on a horizontal floor. The coefficient of static friction between the floor and the block is 0.50, and the coefficient of kinetic friction between the floor and the block is 0.40.

- What is the normal force \( N \) exerted on the block by the floor? (Answer: 196 N.)
- Calculate the maximum static frictional force, \( F_{f,\text{max}} = \mu_s N \), possible between the block and floor. (Answer: 98 N.)
- Calculate the kinetic frictional force, \( F_f = \mu_k N \), between the block and floor if the block moves on the floor. (Answer: 78 N.)
- While the block is initially at rest you exert a horizontal force of 85 N on the block. Will the block move? (Answer: No.)
- While the block is initially at rest you exert a horizontal force of 105 N on the block. Will the block move? If yes, what will be its acceleration? (Answer: Yes, \( a = 1.35 \text{ m/s}^2 \).)

Table 6.1: Approximate coefficients of friction between surfaces.
Lecture-Example 6.2:
A trunk with a weight of 196 N rests on the floor. The coefficient of static friction between the trunk and the floor is 0.50, and the coefficient of kinetic friction is 0.40.

- What is the magnitude of the minimum horizontal force with which a person must push on the trunk to start it moving? (Answer: 98 N.)
- Once the trunk is moving, what magnitude of horizontal force must the person apply to keep it moving with constant velocity? (Answer: 78.4 N.)
- If the person continued to push with the force used to start the motion, what would be the magnitude of the trunk’s acceleration? (Answer: 0.98 m/s².)

Lecture-Example 6.3:
A car is traveling at 70.0 miles/hour (= 31.3 m/s) on a horizontal highway.

- What is the stopping distance when the surface is dry and the coefficient of kinetic friction \( \mu_s \) between road and tires is 0.60? (Answer: 83 m.)
- If the coefficient of kinetic friction between road and tires on a rainy day is 0.40, what is the minimum distance in which the car will stop? (Answer: 125 m.)

Lecture-Example 6.4:
A mass \( m \) is on an incline with coefficient of static friction \( \mu_s = 0.80 \) and coefficient of kinetic friction \( \mu_k = 0.50 \).

- Using Newton’s law determine the equations of motion to be, choosing the \( x \) axis to be parallel to the incline,

\[
\begin{align*}
mg \sin \theta - F_f &= ma_x, \quad (6.2a) \\
N - mg \cos \theta &= 0. \quad (6.2b)
\end{align*}
\]

- Let \( \theta = 30.0^\circ \). Determine the normal force. (Answer: 170 N.) Determine the maximum static frictional force, \( F_{f,\text{max}} = \mu_s N \), possible between the mass and the incline. (Answer: \( F_{f,\text{max}} = 136 \) N.) Find the net force in the lateral direction other than friction. (Answer: \( mg \sin \theta = 98 \) N.) Determine the force of friction on the mass. (Answer: 98 N.) Will the mass move? (Answer: No.)
6.1. FORCE OF FRICTION

- Let $\theta = 45.0^\circ$. Determine the normal force. (Answer: 126 N.) Determine the maximum static frictional force, $F_{f, \text{max}} = \mu_s N$, possible between the mass and the incline. (Answer: $F_{f, \text{max}} = 101$ N.) Find the net force in the lateral direction other than friction. (Answer: $mg \sin \theta = 150$ N.) Will the mass move? (Answer: Yes.) Determine the acceleration of the resultant motion. (Answer: $4.35 \text{ m/s}^2$)

- Critical angle: As the angle of the incline is increased, there is a critical angle when the mass begins to move. For this case the force of friction is equal to the maximum static frictional force, $F_f = \mu_s N$, and the mass is at the verge of moving, $a_x = 0$. Show that the critical angle is given by
  \[ \theta_c = \tan^{-1} \mu_s, \quad (6.3) \]
  which is independent of the mass $m$. (Answer: $\theta_c = 38.7^\circ$.)

- Concept question: Consider the case of a bucket resting on the inclined roof of a house. It starts to rain and the bucket gradually fills with water. Assuming a constant coefficient of static friction between the roof and bucket, no wind, and no tipping, when will the bucket start sliding?

- Concept question: A block is projected up a frictionless inclined plane with initial speed $v_0$. The angle of incline is $\theta = 30.0^\circ$. Will the block slide back down?

Lecture-Example 6.5:
A mass $m$ is held to a vertical wall by pushing on it by a force $\vec{F}$ exerted an angle $\theta$ with respect to the vertical.

![Figure 6.2: Lecture-Example 6.5](image)

- Using Newton’s law determine the equations of motion to be,
  \[ F \sin \theta - N = 0, \quad \text{(6.4a)} \]
  \[ F_f - F \cos \theta - mg = 0. \quad \text{(6.4b)} \]
  Show that the inequality to be satisfied, for the mass to be held up, is given by
  \[ mg \leq F(\cos \theta + \mu_s \sin \theta). \quad \text{(6.5)} \]
Chapter 7

Circular motion

7.1 Centripetal acceleration

From the definition of acceleration, in the instantaneous limit $\Delta t \to 0$,

$$\vec{a} = \frac{\Delta \vec{v}}{\Delta t}, \quad (7.1)$$

we can infer that uniform velocity implies zero acceleration. Here uniform means for constant with respect to time. Here we investigate the case when the magnitude of velocity, $v = |\vec{v}|$, the speed, is uniform, but the direction of speed is not constant in time.

Uniform circular motion

A particle moving in a circle of radius $R$ with uniform speed is termed uniform circular motion. Circular motion is periodic, so we introduce the time period $T$. A related quantity is the inverse of time period, the frequency,

$$f = \frac{1}{T}, \quad (7.2)$$

which is measured in units of revolutions per unit time, or more generally as number of times per unit time. Using the fact that

$$1 \text{ revolution} = 2\pi \text{ radians} \quad (7.3)$$

we define the angular frequency

$$\omega = 2\pi f = \frac{2\pi}{T}. \quad (7.4)$$

Lecture-Example 7.1: A bus comes to a bus stop every 20 minutes. How frequently, in units of times per second, does the bus come to the bus stop? (Answer: 3 times/hour.)

Magnitude of velocity in uniform circular motion

The angular frequency is the rate of change of angle $\theta$ per unit time. Thus, it is also called the angular velocity in the instantaneous limit $\Delta t \to 0$,

$$\omega = \frac{\Delta \theta}{\Delta t}. \quad (7.5)$$

The speed in uniform circular motion

$$v = \frac{2\pi R}{T} = \omega R. \quad (7.6)$$
CHAPTER 7. CIRCULAR MOTION

Direction of velocity in uniform circular motion
Direction of velocity is decided by the direction of change in position $\Delta \vec{r}$ in Fig. 7.1. In the instantaneous limit $\Delta t \to 0$ the instantaneous velocity is tangential to the circle.

Magnitude of acceleration in uniform circular motion
For finite $\Delta t$ we use the similarity of the triangles in Fig. 7.1 to write

$$\frac{|\Delta \vec{v}|}{v} = \frac{|\Delta \vec{r}|}{R}.$$  \hfill (7.7)

The magnitude of the centripetal acceleration is

$$a_c = \lim_{\Delta t \to 0} \frac{|\Delta \vec{v}|}{\Delta t} = \lim_{\Delta t \to 0} \frac{v}{R} \frac{|\Delta \vec{r}|}{\Delta t} = v \omega.$$  \hfill (7.8)

Also, we can derive

$$a_c = \omega^2 R = \frac{v^2}{R} = 4\pi^2 f^2 R = \frac{4\pi^2 R}{T^2}.$$  \hfill (7.9)

Direction of acceleration in uniform circular motion
Direction of acceleration is decided by the direction of change in velocity $\Delta \vec{v}$ in Fig. 7.1. In the instantaneous limit $\Delta t \to 0$ the instantaneous acceleration is radially inward.

Lecture-Example 7.2: (Cloverleaf)
A typical ramp in a cloverleaf interchange design on the interstate has a radius of 50 m. What is the centripetal acceleration of a car exiting an interstate at a speed of 20 m/s ($\sim 45$ miles/hour). (Answer: 8 m/s$^2$.) Compare this to the acceleration due to gravity $g = 9.8$ m/s$^2$.

Lecture-Example 7.3: (Trick riding, see Circus Physics)
In a trick ride a horse is galloping at the speed of 10 m/s, in a circle of radius 6.4 m. What is the centripetal acceleration of the trick rider. (Answer: 16 m/s$^2$.) Compare this to the acceleration due to gravity $g = 9.8$ m/s$^2$.

Lecture-Example 7.4: (20-G centrifuge, check out this YouTube video.)
The 20-G centrifuge of NASA has a radius of 29 feet (8.8 m). What is the centripetal acceleration at the outer edge of the tube while the centrifuge is rotating at 0.50 rev/sec? (Answer: 9 g.) What is the centripetal acceleration at 0.70 rev/sec? (Answer: 17 g.) Note that such high acceleration causes damage to capillaries, see Table 2.3.

**Lecture-Example 7.5:** (Gravitropism)
The root tip and shoot tip of a plant have the ability to sense the direction of gravity, very much like smartphones. That is, root tips grow along the direction of gravity, and shoot tips grow against the direction of gravity. (These are associated to statocytes.) Discuss the direction of growth of a plant when placed inside a centrifuge. What if the plant is in zero-gravity? Check out this YouTube video.

**Lecture-Example 7.6:** (Variation in $g$)
The acceleration due to gravity is given by, (as we shall derive later in the course,)

$$g = \frac{G M_E}{R_E^2} = 9.82 \frac{m}{s^2},$$

(7.10)

where $M_E = 5.97 \times 10^{24}$ kg and $R_E = 6.37 \times 10^6$ m are the mass and radius of the Earth respectively and $G = 6.67 \times 10^{-11}$ Nm$^2$/kg$^2$ is a fundamental constant. This relation does not take into account the rotation of the Earth about its axis and assumes that the Earth is a perfect sphere.

- The centripetal acceleration at a latitude $\phi$ on the Earth is given by

$$\frac{4\pi^2}{T_E^2} R_E = 0.034 \cos \phi,$$

(7.11)

where $T_E = 24$ hours is the time period of the Earth’s rotation about its axis. It is directed towards the axis of rotation. The component of this acceleration toward the center of the Earth is obtained by multiplying with another factor of $\cos \phi$. The contribution to $g$ from the rotation of the Earth is largest at the equator and zero at the poles.

- The rotation of the Earth has led to its equatorial bulge, turning it into an oblate spheroid. That is, the radius of the Earth at the equator is about 20 km longer than at the poles. This in turn leads to a weaker $g$ at the equator. The fractional change in gravity at a height $h$ above a sphere is approximately, for $h \ll R$, given by $2h/R$. For $h = 42$ km this leads to a contribution of 0.065 m/s$^2$.

- Contribution to $g$ from rotation of the Earth is positive, and from the equatorial bulge is negative. Together, this leads to the variations in $g$ on the surface of the Earth. Nevertheless, the variations in $g$ are between 9.76 m/s$^2$ (in the Nevado summit in Peru) and 9.84 m/s$^2$ (in the Arctic sea), refer this article in Geophysical Research Letters (2013). The measurement of $g$ is relevant for determining the elevation of a geographic location on the Earth. An interesting fact is that even though Mount Everest is the highest elevation above sea level, it is the summit of Chimborazo in Ecuador that is farthest from the center of the Earth.

### 7.2 Uniform circular motion

A particle uniformly moving along a circular path is accelerating radially inward, given by

$$\ddot{\mathbf{a}} = -\frac{v^2}{R} \hat{r},$$

(7.12)
where \( \hat{r} \) is a unit vector pointing radially outward, \( R \) is the radius of the circle, and \( v \) is the magnitude of the uniform velocity. Newton’s law then implies that the sum of the total force acting on the system necessarily has to point radially inward.

**Lecture-Example 7.7:**
A stuntman drives a car over the top of a hill, the cross section of which can be approximated by a circle of radius \( R = 250 \text{ m} \). What is the greatest speed at which he can drive without the car leaving the road at the top of the hill?

![Figure 7.2: Lecture-Example 7.7](image)

**Lecture-Example 7.8:**
A turntable is rotating with a constant angular speed of 6.5 rad/s. You place a penny on the turntable.

- List the forces acting on the penny.
- Which force contributes to the centripetal acceleration of the penny?
- What is the farthest distance away from the axis of rotation of the turntable that you can place a penny such that the penny does not slide away? The coefficient of static friction between the penny and the turntable is 0.5.

**Lecture-Example 7.9:** (Motorcycle stunt)
In the Globe of Death stunt motorcycle stunt riders ride motorcycles inside a mesh globe. In particular, they can loop vertically. Consider a motorcycle going around a vertical circle of radius \( R \), inside the globe, with uniform velocity. Determine the normal force and the force of friction acting on the motorcycle as a function of angle \( \theta \) described in Figure 7.3.

- Using Newton’s Laws we have the equations of motion, along the radial and tangential direction to the circle, given by

\[
N = \frac{mv^2}{R} - mg \cos \theta, \quad (7.13a)
\]

\[
F_f = mg \sin \theta. \quad (7.13b)
\]

- Investigate the magnitude and direction of the normal and force of friction as a function of angle \( \theta \). In particular, determine these forces for \( \theta = 0, -90^\circ, 90^\circ \). Verify that, while at \( \theta = 90^\circ \), the motorcycle can not stay there without falling off unless the the centripetal acceleration is sufficiently high, that is, \( \frac{mv^2}{R} \geq mg \).
7.3 Banking of roads

Motorized cars are all around us, and we constantly encounter banked roads while driving on highways bending along a curve. A banked road is a road that is appropriately inclined, around a turn, to reduce the chances of vehicles skidding while maneuvering the turn. Banked roads are more striking in the case of racetracks on which the race cars move many times faster than typical cars on a highway. Nevertheless, this ubiquitous presence of banked roads around us does not lessen the appreciation for this striking application of Newton’s laws.

Unbanked frictionless surface

A car cannot drive in a circle on an unbanked frictionless surface, because there is no horizontal force available to contribute to the (centripetal) acceleration due to circular motion.

Unbanked surface with friction

Consider a car moving with uniform speed along a circular path of radius $R$ on a flat surface with coefficient of static friction $\mu_s$. Using Newton’s laws we have the equations of motion

\[
F_f = \frac{mv^2}{R}, \quad \text{(7.14a)}
\]

\[
N = mg, \quad \text{(7.14b)}
\]

where $F_f \leq \mu_s N$. The maximum speed the car can achieve without sliding is given by

\[
v_{\text{max}}^2 = gR \tan \theta_s, \quad \text{(7.15)}
\]

where we used the definition of friction angle $\mu_s = \tan \theta_s$.

Banked frictionless surface

Let the surface make an angle $\theta$ with respect to the horizontal. Even though there is no friction force due to the geometry of the banking the normal force is able to provide the necessary centripetal acceleration. Using Newton’s laws we have the equations of motion

\[
N \sin \theta = \frac{mv^2}{R}, \quad \text{(7.16a)}
\]

\[
N \cos \theta = mg. \quad \text{(7.16b)}
\]

The speed of the car is given by

\[
v^2 = gR \tan \theta. \quad \text{(7.17)}
\]

Thus, if the car speeds up it automatically gets farther away and vice versa.
CHAPTER 7. CIRCULAR MOTION

Banked surface with friction

Let us now consider the case of a banked surface with friction. In this case both the normal force and the force of friction are available to contribute to the centripetal acceleration. There now exists a particular speed \( v_0 \) that satisfies

\[
v_0^2 = gR \tan \theta,
\]

(7.18)

for which case the normal force alone completely provides the necessary centripetal force and balances the force of gravity, see Figure 7.4. Thus, in this case, the frictional force is completely absent, as illustrated in Figure 7.4. The physical nature of the problem, in the sense governed by the direction of friction, switches sign at speed \( v_0 \).

\[
\begin{array}{c}
\text{Figure 7.4: Forces acting on a car moving on a banked road. The car is moving into the page. The direction of friction is inward for } v_0 < v \leq v_{\text{max}}, \text{ outward for } v_{\text{min}} < v < v_0, \text{ and zero for } v = v_0. \\
\end{array}
\]

Let us begin by investigating what happens when the car deviates from this speed \( v_0 \)? If the speed of the car is different from \( v_0 \), the normal force alone cannot provide the necessary centripetal acceleration without sliding. Thus, as a response, the frictional force gets switched on. The frictional force responds to act (inwards) when the car moves faster than \( v_0 \); this provides the additional force necessary to balance the centripetal force, see Figure 7.4. Similarly, the frictional force acts in the negative direction (outwards) when the car moves slower than \( v_0 \), see Figure 7.4. Let the frictional force be represented by \( F_f \). Thus, for the case when the frictional force is acting inward, we have the equations of motion for the car given by,

\[
\begin{align}
N \sin \theta + F_f \cos \theta &= \frac{mv^2}{R}, \quad (7.19a) \\
N \cos \theta - F_f \sin \theta &= mg. \quad (7.19b)
\end{align}
\]

The equations of motion for the car when the frictional force is acting outward are given by Eqs. (7.19) by changing the sign of \( F_f \). Can the frictional force together with the normal force balance the centripetal force for all speeds? No. There exists an upper threshold to speed \( v_{\text{max}} \) beyond which the frictional force fails to balance the centripetal force, and it causes the car to skid outward. Similarly, there exists a lower threshold to speed \( v_{\text{min}} \) below which the car skids inward. To this end it is convenient to define

\[
F_f \leq \mu_s N, \quad \mu_s = \tan \theta_s, \quad (7.20)
\]

where \( \mu_s \) is the coefficient of static friction, and \( \theta_s \) is a suitable reparametrization of the coefficient of static friction. The upper threshold for the speed is obtained by using the equality of Eq. (7.20) in Eq. (7.19) to yield

\[
v_{\text{max}}^2 = rg \tan(\theta + \theta_s), \quad (7.21)
\]

where we used the definition in Eq. (7.20) and the trigonometric identity for the tangent of the sum of two angles. Similarly, the lower threshold for the speed below which the car slides inward is given by

\[
v_{\text{min}}^2 = rg \tan(\theta - \theta_s). \quad (7.22)
\]
In summary, at any given point on the surface of the cone, to avoid skidding inward or outward in the radial direction, the car has to move within speed limits described by

\[ v_{\text{min}} \leq v \leq v_{\text{max}}. \]  

(7.23)
Chapter 8

Work and Energy

8.1 Scalar product

Scalar product of two vectors

\[ \vec{A} = A_x \hat{i} + A_y \hat{j} + A_z \hat{k}, \]  
\[ \vec{B} = B_x \hat{i} + B_y \hat{j} + B_z \hat{k}, \]  
where \( \theta \) is the angle between the two vectors. The scalar product is a measure of the component of one vector along another vector.

8.2 Work-energy theorem

Starting from Newton’s law

\[ \vec{F}_1 + \vec{F}_2 + \ldots = m\vec{a}, \]  
and integrating on both sides along the path of motion, we derive the work-energy theorem

\[ W_1 + W_2 + \ldots = \Delta K, \]  
where \( W_i \) is the work done by the force \( \vec{F}_i, (i = 1, 2, \ldots) \) and \( \Delta K \) is the change in kinetic energy.

Work done by a force

Work done by a force \( \vec{F} \) on mass \( m \) while displacing it from an initial point \( \vec{r}_i \) to a final \( \vec{r}_f \), along a path \( P \), is given by

\[ W = \sum_{P} \Delta \vec{r} \cdot \vec{F}. \]  

Kinetic energy

The energy associated with the state of motion, the kinetic energy, is

\[ K = \frac{1}{2}mv^2, \]
where \( v \) is the magnitude of the velocity of mass \( m \).

**Lecture-Example 8.1:** (Area under the force-position graph.)
Consider the motion of a mass \( m \) under the action of a force
\[
F = -kx,
\]
where \( k \) is a constant. Show that the work done by the force is equal to the area under the force-position graph.

\[ W = \sum_{i} (-kx) \Delta x = -\frac{1}{2}k(x_f^2 - x_i^2). \]  

\[ W = \frac{1}{2}k(x_f - x_i)^2 - kx_i(x_f - x_i). \]

**Lecture-Example 8.2:**
Consider a mass \( m = 25\) kg being pulled by a force \( F_{\text{pull}} = 80.0\) N, exerted horizontally, such that the mass moves, on a horizontal surface with coefficient of kinetic friction \( \mu_k = 0.30 \). Assume that the mass starts from rest. We would like to determine the final velocity \( v_f \) after the mass has moved a horizontal distance \( d = 10.0 \) m.

- We identify four forces acting on the mass and write Newton’s law for the configuration as
  \[
  m\ddot{\mathbf{g}} + \mathbf{N} + F_{\text{pull}} + F_f = m\ddot{\mathbf{a}}.
  \]
- Work done by the individual force are
  \[
  W_{\text{pull}} = F_{\text{pull}}d \cos 0 = F_{\text{pull}}d = 800\ J, \]
  \[
  W_{g} = mgd \cos 90 = 0\ J, \]
  \[
  W_{N} = Nd \cos 90 = 0\ J, \]
  \[
  W_f = F_f d \cos 180 = -F_f d = -\mu_k Nd = -\mu_k mgd = -735\ J,
  \]
where we used \( F_f = \mu_k N \), and then used Newton’s law in the vertical \( y \)-direction to learn that \( N = mg \).
8.2. WORK-ENERGY THEOREM

The total work done by the sum of all the forces is

\[ W_{\text{pull}} + W_{g} + W_{N} + W_{f} = F_{\text{pull}}d - \mu_{k}mgd = 65 \text{ J}. \]  

(8.12)

Using the work-energy theorem and using \( v_i = 0 \) we have

\[ W_{\text{pull}} + W_{g} + W_{N} + W_{f} = \frac{1}{2}mv_f^2. \]  

(8.13)

Using Eq. (8.12) we then have

\[ F_{\text{pull}}d - \mu_{k}mgd = \frac{1}{2}mv_f^2. \]  

(8.14)

Substituting numbers we can determine \( v_f = 2.28 \text{ m/s}. \)

Lecture-Example 8.3:
Consider a mass \( m = 25 \text{ kg} \) being pulled by a force \( F_{\text{pull}} = 80.0 \text{ N} \), exerted along a line making angle \( \theta = 30.0^\circ \) above the horizontal, such that the mass moves, on a horizontal surface with coefficient of kinetic friction \( \mu_k = 0.30 \). Assume that the mass starts from rest. Determine the final velocity \( v_f \) after the mass has moved a horizontal distance \( d = 10.0 \text{ m} \).

The work done by the individual forces are

\[ W_{\text{pull}} = F_{\text{pull}}d \cos \theta = 693 \text{ J}. \]  

(8.15a)

\[ W_{g} = mgd \cos 90^\circ = 0 \text{ J}. \]  

(8.15b)

\[ W_{N} = Nd \cos 90^\circ = 0 \text{ J}. \]  

(8.15c)

\[ W_{f} = F_{f}d \cos 180^\circ = -\mu_{k}Nd = -\mu_{k}(mg - F_{\text{pull}} \sin \theta)d = -615 \text{ J}. \]  

(8.15d)

We used \( N = mg - \mu_{k}F_{\text{pull}} \sin \theta \), a deduction from the \( y \)-component of Newton’s law.
CHAPTER 8. WORK AND ENERGY

• Using the work energy theorem we obtain

\[ K_f = F_{\text{pull}} d (\cos \theta + \mu_k \sin \theta) - \mu_k m g d, \tag{8.16} \]

which leads to \( v_f = 2.50 \text{ m/s} \).

Lecture-Example 8.4:
A mass \( m = 25 \text{ kg} \) slides down an inclined plane with angle \( \theta = 30.0^\circ \). Assume coefficient of kinetic friction \( \mu_k = 0.30 \). Assume that the mass starts from rest. Determine the final velocity \( v_f \) after the mass has moved a distance \( d = 10.0 \text{ m} \) along the incline.

• Determine the work done by the three individual forces.

• Using the work-energy theorem deduce

\[ K_f = m g d \sin \theta - \mu_k m g d \cos \theta. \tag{8.17} \]

This leads to \( v_f = 6.86 \text{ m/s} \).

• Observe that the final velocity is independent of mass \( m \).

8.3 Conservative forces and potential energy

The work done by a conservative force is independent of the path taken by the mass. Thus, the work done by a conservative force is completely determined by the initial and final position of the mass. That is, the work done by the force is conveniently defined as the negative change in potential energy \( U \) associated with the conservative force,

\[ W = \sum_i \Delta \vec{r} \cdot \vec{F} = -\Delta U. \tag{8.18} \]

The work-energy theorem, with emphasis on this distinction, is

\[ (W_1^{nc} + W_2^{nc} + \ldots) + (W_1^c + W_2^c + \ldots) = \Delta K, \tag{8.19} \]

where ‘nc’ in superscript stands for non-conservative force and ‘c’ in superscript stands for conservative force. It is then expressed in the form

\[ (W_1^{nc} + W_2^{nc} + \ldots) = \Delta K + (\Delta U_1 + \Delta U_2 + \ldots). \tag{8.20} \]

Thus, if there are no non-conservative forces acting on the system, the change in energy of the system is independent of the path and is completely determined by the initial and final positions.

Gravitational potential energy

The force of gravity is a conservative force. The work done by the gravitational force is completely determined by the change in height of the mass \( m \),

\[ W_g = -m g \Delta y = -\Delta U_g, \tag{8.21} \]

where \( \Delta y = y_f - y_i \). It depends only on the initial and final heights. Thus, it is conveniently expressed in terms of the gravitational potential energy function

\[ U_g = m g y. \tag{8.22} \]

Lecture-Example 8.5:
8.3. CONSERVATIVE FORCES AND POTENTIAL ENERGY

- Determine the work done by force of gravity in the following processes.
  1. A person lifts a $m = 3.0$ kg block a vertical distance $h = 10.0$ m and then carries the block horizontally a distance $x = 50.0$ m.
  2. A person carries the block horizontally a distance $x = 50.0$ m and then lifts it a vertical distance $h = 10.0$ m.
  3. A person carries the block along the diagonal line.

- Observe that the work done by the force of gravity is independent of the path. Observe that the work done by force of gravity is zero along a closed path. Observe that the force of gravity does not do any work while moving horizontally. An arbitrary path can be broken into vertical and horizontal sections, which corresponds to path independence.

Lecture-Example 8.6:
A mass of $m = 25.0$ kg slides down a frictionless incline that makes an angle of $\theta = 30.0^\circ$ with the horizontal. Assume that the mass starts from rest. The two forces acting on the mass during the slide are the normal force and the force of gravity. The mass slides $d = 10.0$ m along the incline.

- Work-energy theorem states
  \[ W_N + W_g = \Delta K. \]  
  \[ \text{(8.23)} \]

  The work done by the normal force is zero,
  \[ W_N = 0. \]  
  \[ \text{(8.24)} \]

  The work done by the force of gravity on the mass is
  \[ W_g = mgd\cos(90^\circ - \theta) = mgd\sin \theta = 1225 \text{ J}. \]  
  \[ \text{(8.25)} \]

- The change in gravitational potential energy is
  \[ \Delta U_g = -W_g = -1225 \text{ J}. \]  
  \[ \text{(8.26)} \]

  Since $W_N = 0$, the change in kinetic energy of the mass is equal to the work done by the force of gravity,
  \[ \Delta K = W_g = 1225 \text{ J}. \]  
  \[ \text{(8.27)} \]

  The velocity of the mass at the end of the slide is then determined to be $9.90$ m/s.

Lecture-Example 8.7: (Roller coaster)
A roller coaster of mass $m = 500.0$ kg moves on the curve described in Figure 8.4. Assume frictionless surface. It starts from rest, $v_A = 0$ m/s at point A height $h_A = 40.0$ m.

- Work-energy theorem states
  \[ W_N + W_g = \Delta K. \]  
  \[ \text{(8.28)} \]

  Show that the work done by the normal force is zero, $W_N = 0$. Thus, conclude
  \[ \Delta K + \Delta U_g = 0, \quad \text{or} \quad K_i + U_i = K_f + U_f. \]  
  \[ \text{(8.29)} \]

- Determine the velocity of the mass at points A to G, given $h_B = 20.0$ m, $h_C = 30.0$ m, $h_D = 10.0$ m, $h_E = 20.0$ m, $h_F = 0$ m, $h_G = 45.0$ m. (Answer: See Table 8.1.) Note that the above results are independent of the mass.
Table 8.1: Lecture-Example 8.7.

• The roller coaster will not reach the point G because it does not have sufficient total energy.

Lecture-Example 8.8:
Figure 8.5 shows a pendulum of length $L = 3.0 \text{ m}$ and mass $m = 5.0 \text{ kg}$. It starts from rest at angle $\theta = 30.0^\circ$. Determine the velocity of the mass when $\theta = 0$.

\begin{figure}[h]
\centering
\includegraphics[width=0.2\textwidth]{figure8.5.png}
\caption{Lecture-Example 8.8.}
\end{figure}

• Work-energy theorem states

$$W_T + W_g = \Delta K. \quad (8.30)$$

Show that the work done by the tension in the rod is zero,

$$W_T = 0. \quad (8.31)$$
Using $h = L - L \cos \theta$, we have

$$mgh_i + K_i = mgh_f + K_f.$$  \hspace{1cm} (8.32)

- How much work does its weight do on the ball?
- What is the change in the gravitational potential energy of the ball Earth system?
- What is the kinetic energy of the ball at its lowest point?
- What is the velocity of the ball at its lowest point?
- If mass $m$ were doubled, would the velocity of the ball at its lowest point increase, decrease, or remain same?

**Elastic potential energy of a spring**

Elastic materials, for example a spring, when stretched exhibit a restoring force in the opposite direction of the stretch. This is stated as Hooke’s law,

$$F = -kx,$$  \hspace{1cm} (8.33)

where for the case of springs $k$ is a material dependent quantity called the spring constant. The work done by an elastic force is

$$W_s = \sum_{i}^f (-kx) \Delta x = - \left( \frac{1}{2} kx_f^2 - \frac{1}{2} kx_i^2 \right).$$  \hspace{1cm} (8.34)

Thus, using $W = -\Delta U$, we read out the elastic potential energy function

$$U_s = \frac{1}{2} kx^2.$$  \hspace{1cm} (8.35)

**Lecture-Example 8.9:** (Spring constant)

A mass of 5.0 kg is hung using a spring. At equilibrium the spring is stretched 5.0 cm. Determine the spring constant.

- At equilibrium the force of gravity balances the elastic restoring force,

$$kx = mg.$$  \hspace{1cm} (8.36)

(Answer: $k = 980 \sim 10^3 \text{N/m}$.) This could be the spring constant of a spring in a simple weighing scale.

- A car weighing 2000 kg is held by four shock absorbers. Thus, each spring gets a load of 500 kg. At equilibrium if the spring is stretched by 5.0 cm, determine the spring constant of a typical shock absorber.
  (Answer: $k \sim 10^5 \text{N/m}$.)

**Lecture-Example 8.10:**

A mass $m$ slides down a frictionless incline, starting from rest at point $A$. After sliding down a distance $L$ (along the incline) it hits a spring of spring constant $k$ at point $B$. The mass is brought to rest at point $C$ when the spring is compressed by length $x$. See Figure 8.6.
• Using work-energy theorem we have
  \[ W_N + W_g + W_s = \Delta K. \]  
  (8.37)

Show that the work done by the normal force is zero, \( W_N = 0 \). Thus, derive

\[ K_A + U_A^g + U_A^s = K_B + U_B^g + U_B^s = K_C + U_C^g + U_C^s. \]  
(8.38)

• Show that the velocity of the mass at point \( B \) is given by
  \[ v_B^2 = 2gL \sin \theta. \]  
(8.39)

• Show that the maximum compression \( x \) in the spring at point \( C \) is given by the quadratic equation,
  \[ x^2 - 2x_0x - 2x_0L = 0, \]  
(8.40)
in terms of the compression \( x_0 \) in the spring at equilibrium, given by

\[ x_0 = \frac{mg}{k} \sin \theta. \]  
(8.41)

Thus, we have

\[ x = x_0 \pm \sqrt{x_0(x_0 + 2L)}. \]  
(8.42)

For \( x_0 \ll 2L \), show that the solution has the limiting form
  \[ x \sim \sqrt{2x_0L}. \]  
(8.43)

For \( 2L \ll x_0 \), show that the solution has the limiting form \( x \sim L \).

---

**Lecture-Example 8.11:**

A mass \( m = 20.0 \text{ kg} \) slides down a frictionless incline, starting from rest at point \( A \) at height \( h = 1.0 \text{ m} \). After sliding down the incline it moves horizontally on a frictionless surface before coming to rest by compressing a spring of spring constant \( k = 2.0 \times 10^4 \text{ N/m} \) by a length \( x \). See Figure 8.7.

• Using work-energy theorem we have
  \[ W_N + W_g + W_s = \Delta K. \]  
(8.44)

Show that the work done by the normal force is zero, \( W_N = 0 \). Thus, derive

\[ K_A + U_A^g + U_A^s = K_B + U_B^g + U_B^s = K_C + U_C^g + U_C^s. \]  
(8.45)

• Determine the velocity of the mass at point \( B \). (Answer: \( 4.4 \text{ m/s} \).)

• Determine the maximum compression \( x \) in the spring. (Answer: \( 14 \text{ cm} \).)
Figure 8.7: Lecture-Example 8.11
Chapter 9

Collisions: Conservation of linear momentum

9.1 Momentum

Using the definition of momentum,
\[ \vec{p} = m\vec{v}, \]  
(9.1)

Newton’s laws can be expressed in the form
\[ \vec{J}_1 + \vec{J}_2 + \ldots = \Delta \vec{p}, \]  
(9.2)

where
\[ \vec{J}_i = \sum \vec{F}_i \Delta t \]  
(9.3)

is the impulse due to force \( \vec{F}_i \).

Lecture-Example 9.1: When a ball of mass \( m_1 = 1.00 \text{kg} \) is falling (on Earth of mass \( m_2 = 5.97 \times 10^{24} \text{kg} \)) what are the individual accelerations of the ball and Earth?

Lecture-Example 9.2: A student of mass \( m = 60.0 \text{kg} \) jumps off a table at height \( h = 1.00 \text{m} \). While hitting the floor he bends his knees such that the time of contact is 100.0 ms. What is the force exerted by the floor on you? If the student does not bend his knees the time of contact is 10.0 ms. What is the new force exerted by the floor now? (Answer: 2660 N versus 26600 N.)

Lecture-Example 9.3: A drop of rain and a pellet of hail, of the same mass \( m = 1.00 \text{g} \), hits the roof of a car with the same speed \( v = 5.00 \text{m/s} \). Rain drop being liquid stays in contact with the roof for 100.0 ms, while hail being solid rebounds (assume with same speed \( v = 5.00 \text{m/s} \)) and thus stays in contact for a mere 1.00 ms. Calculate the force exerted by each on the roof of the car. (The numbers quoted here are based on reasonable guesses, and could be off by an order of magnitude.)
9.2 Conservation of linear momentum

If the net external force on a system is zero the change in momentum is zero, or the momentum is conserved. In a collision involving two masses we can write

\[ \mathbf{F}^\text{ext}_1 + \mathbf{C}_{12} = \frac{\Delta \mathbf{p}_1}{\Delta t}, \quad (9.4) \]
\[ \mathbf{F}^\text{ext}_2 + \mathbf{C}_{21} = \frac{\Delta \mathbf{p}_2}{\Delta t}, \quad (9.5) \]

where \( \mathbf{C}_{12} \) and \( \mathbf{C}_{21} \) are contact forces, which are action-reaction pairs that are equal and opposite in directions. If the external forces add up to zero there is no change in momentum and we have the conservation of linear momentum

\[ \mathbf{p}_1 + \mathbf{p}_2 = \mathbf{p}_1' + \mathbf{p}_2'. \quad (9.6) \]

9.2.1 Inelastic collisions

Using conservation of linear momentum we have

\[ m_1 \mathbf{v}_{1i} + m_2 \mathbf{v}_{2i} = m_1 \mathbf{v}_{1f} + m_2 \mathbf{v}_{2f}. \quad (9.7) \]

The particular case when the masses entangle together before or after the collision is called a completely inelastic collision.

Lecture-Example 9.4:
A shooter of mass \( m_2 = 90.0 \text{ kg} \) shoots a bullet of mass \( m_1 = 3.00 \text{ g} \) horizontally, standing on a frictionless surface at rest. If the muzzle velocity of the bullet is \( v_{1f} = 600.0 \text{ m/s} \), what is the recoil speed of the shooter? (Answer: \( v_{2f} = -2.00 \text{ cm/s} \).)

Lecture-Example 9.5:
A shooter of mass \( m_2 = 90.0 \text{ kg} \) shoots a bullet of mass \( m_1 = 3.00 \text{ g} \) in a direction \( \theta = 60.0^\circ \) with respect to the horizontal, standing on a frictionless surface at rest. If the muzzle velocity of the bullet is \( v_{1f} = 600.0 \text{ m/s} \), what is the recoil speed of the shooter? (Answer: \( v_{2f} = -1.00 \text{ cm/s} \).)

Lecture-Example 9.6: (Ballistic pendulum)
A bullet with mass \( m_1 = 3.00 \text{ g} \) is fired into a wooden block of mass \( m_2 = 1.00 \text{ kg} \), that hangs like a pendulum. The bullet is embedded in the block (complete inelastic collision). The block (with the bullet embedded in it) goes \( h = 30.0 \text{ cm} \) high after collision. Calculate the speed of the bullet before it hit the block.

Lecture-Example 9.7: (Collision of automobiles at an intersection.)
A car of mass \( m_1 = 2000.0 \text{ kg} \) is moving at speed \( v_{1i} = 20.0 \text{ m/s} \) towards East. A truck of mass \( m_2 = 5000.0 \text{ kg} \) is moving at speed \( v_{2i} = 10.0 \text{ m/s} \) towards North. They collide at an intersection and get entangled (complete inelastic collision). What is the magnitude and direction of the final velocity of the entangled automobiles?

- Repeat the calculation for a semi-truck (ten times heavier) moving at the same speed.
9.2.2 Elastic collisions in 1-D

In an elastic collision, in addition to momentum being conserved, the kinetic energy is also conserved. This requires no loss of energy in the form of sound and heat. Conservation of kinetic energy leads to

\[
\frac{1}{2} m_1 v_{1i}^2 + \frac{1}{2} m_2 v_{2i}^2 = \frac{1}{2} m_1 v_{1f}^2 + \frac{1}{2} m_2 v_{2f}^2. \tag{9.8}
\]

In conjunction with the conservation of momentum,

\[
m_1 v_{1i} + m_2 v_{2i} = m_1 v_{1f} + m_2 v_{2f}, \tag{9.9}
\]

this leads to the corollary

\[
v_{1i} + v_{1f} = v_{2i} + v_{2f}. \tag{9.10}
\]

Together we can solve for the final velocities:

\[
v_{1f} = \frac{m_1 - m_2}{m_1 + m_2} v_{1i} + \frac{2m_2}{m_1 + m_2} v_{2i}, \tag{9.11a}
\]

\[
v_{2f} = \frac{2m_1}{m_1 + m_2} v_{1i} + \frac{m_2 - m_1}{m_1 + m_2} v_{2i}. \tag{9.11b}
\]

Consider the following cases:

1. \( m_1 = m_2 \): Implies swapping of velocities!
2. \( v_{2i} = 0 \):
3. \( v_{2i} = 0, m_1 \ll m_2 \):
4. \( v_{2i} = 0, m_1 \gg m_2 \):

---

**Lecture-Example 9.8:** A mass \( m_1 = 1.00 \text{ kg} \) moving with a speed \( v_{1i} = +10.0 \text{ m/s} \) (elastically) collides with another mass \( m_2 = 1.00 \text{ kg} \) initially at rest. Describe the motion after collision. (Answer: \( v_{1f} = 0 \text{ m/s} \) and \( v_{2f} = -v_{1i} = +10.0 \text{ m/s}. \))

---

**Lecture-Example 9.9:** A mass \( m_1 = 1.00 \text{ kg} \) moving with a speed \( v_{1i} = +10.0 \text{ m/s} \) (elastically) collides with another mass \( m_2 = 100.0 \text{ kg} \) initially at rest. Describe the motion after collision. (Answer: \( v_{1f} = -9.80 \text{ m/s} \) and \( v_{2f} = +0.198 \text{ m/s}. \))

---

**Lecture-Example 9.10:** A mass \( m_1 = 100 \text{ kg} \) moving with a speed \( v_{1i} = +10 \text{ m/s} \) (elastically) collides with another mass \( m_2 = 1 \text{ kg} \) initially at rest. Describe the motion after collision. (Answer: \( v_{1f} = +9.80 \text{ m/s} \) and \( v_{2f} = +19.8 \text{ m/s}. \))

---

**Lecture-Example 9.11:** (Rebound of tennis ball on basketball.)
A tennis ball of mass \( m_1 = 60.0 \text{ g} \) is dropped with a basketball of mass \( m_2 = 0.600 \text{ kg} \) from a height of \( h = 1 \text{ m} \). How high does the tennis ball return back?
Lecture-Example 9.12: An electron collides elastically with a stationary hydrogen atom. The mass of the hydrogen atom is 1837 times that of the electron. Assume that all motion, before and after the collision, occurs along the same straight line. What is the ratio of the kinetic energy of the hydrogen atom after the collision to that of the electron before the collision?

Using Eqs. (9.11) for elastic collisions in 1-D, with \( m_2 = 1837m_1 \) and \( v_{2i} = 0 \), obtain

\[
\frac{v_{2f}}{v_{1i}} = \frac{2}{1838}.
\]

Then, we have the ratio

\[
\frac{K_{2f}}{K_{1i}} = \frac{m_2}{m_1} \left( \frac{v_{2f}}{v_{1i}} \right)^2 = 1837 \left( \frac{2}{1838} \right)^2 \sim \frac{1}{459.8}.
\]

\( \text{(9.13)} \)

9.3 Center of mass

The center of mass of a distribution of mass (in one dimension) is defined as

\[
x_{\text{cm}} = \frac{\sum_{i=1}^{N} m_i x_i}{\sum_{i=1}^{N} m_i}.
\]

(9.14)

In the language of statistics, center of mass is the first moment of mass. The total mass itself is the zeroth moment of mass. The term weighted average is based on this concept. In three dimensions the center of mass of a distribution of mass is defined as

\[
\vec{r}_{\text{cm}} = \frac{\sum_{i=1}^{N} m_i \vec{r}_i}{\sum_{i=1}^{N} m_i}.
\]

(9.15)

Lecture-Example 9.13: (Meter stick)

A uniform meter stick has a mass \( m_1 = 10.0 \) kg placed at 100.0 cm mark and another mass \( m_2 = 20.0 \) kg placed at 20.0 cm mark. Determine the center of mass of the stick and the two masses together. (Answer: \( x_{\text{cm}} = 46.7 \) cm.)

Lecture-Example 9.14: (Earth-Moon)

Determine the center of mass of the Earth-Moon system. In particular, determine if the center of mass of the Earth-Moon system is inside or outside the Earth. Given the masses \( M_{\text{Earth}} = 5.97 \times 10^{24} \) kg, \( M_{\text{Moon}} = 7.35 \times 10^{22} \) kg, the radiiues \( R_{\text{Earth}} = 6.37 \times 10^6 \) m, \( R_{\text{Moon}} = 1.74 \times 10^6 \) m, and the distance between them is \( r = 384 \times 10^6 \) m. (Answer: \( 4.67 \times 10^6 \) m from the center of Earth on the line passing through the centers of Earth and Moon.)

Lecture-Example 9.15:

Three masses are placed on a plane such that the coordinates of the masses are, \( m_1 = 1.0 \) kg at \((1, 0)\), \( m_2 = 2.0 \) kg at \((2, 0)\), and \( m_3 = 3.0 \) kg at \((0, 3)\). Determine the coordinates of the center of the mass of the three masses. (Answer: \( \left( \frac{5}{3}, \frac{4}{3} \right) \).)
Part II

Electricity and Magnetism
Chapter 18

Electric force and electric Field

18.1 Electric charge

Like mass is a fundamental property of an object, electric charge is another fundamental property of an object or a particle. Unlike mass, which is always non-negative, charge can be positive or negative. Charge is measured in units of Coulomb.

1. Electric charge is always conserved.

2. Electric charge is quantized. That is, it always comes in integer multiples of a fundamental charge

\[ e \sim 1.60 \times 10^{-19} \text{ C.} \]

(18.1)

It is instructive to compare the electric charge and mass of the three particles that constitutes all atoms.

<table>
<thead>

</tr>
<tr>
<td>Neutron</td>
<td>0</td>
<td>$\sim 1.674 \times 10^{-27} \text{ kg}$</td>
</tr>
</tbody>
</table>

3. All macroscopic objects get their charge from the electrons and protons that constitute them. Charges are not always free to move inside an object. We will often imagine two extremes: A perfect conductor in which the charges are completely free to move, and a perfect insulator in which the charges are static. Metals (like gold and copper) are close to perfect conductors, and wood and rubber are close to perfect insulators. Vacuum is the perfect insulator.

To get an an insight of the amount of charge contained in a Coulomb of charge we list a few typical charges we encounter in Table 18.1.

Lecture-Example 18.1:
Determine the number of electrons in one gram of electron. Then calculate the total charge of one gram of electron.

• One gram of electron has about $10^{30}$ electrons, and a total charge of about $10^{11}$ C, an enormous amount of charge.

• One gram of proton has about $10^{27}$ protons, and a total charge of about $10^{8}$ C.
### Table 18.1: Orders of magnitude (charge)

<table>

<td>this much isolated charge when confined to a region of 1 m has been predicted to breakdown vacuum.</td>
</tr>
</tbody>
</table>

### 18.2 Coulomb’s law

The electrostatic force between two objects with charges $q_1$ and $q_2$, separated by distance $r$, is

$$\vec{F} = k_e \frac{q_1 q_2}{r^2} \hat{r}, \quad (18.2)$$

where $\hat{r}$ encodes the direction content of the force. The constant of proportionality is $k_e \sim 8.99 \times 10^9 \text{Nm}^2/C^2$, which is often expressed in terms the permittivity of vacuum,

$$\varepsilon_0 \sim 8.85 \times 10^{-12} \frac{\text{C}^2}{\text{Nm}^2}, \quad \text{using} \quad k_e = \frac{1}{4\pi\varepsilon_0}. \quad (18.3)$$

**Lecture-Example 18.2:** (Static electricity)

Consider a neutral balloon of mass $m = 10.0 \text{ g}$ blown up so that it is a sphere of radius $R = 10.0 \text{ cm}$. I can rub it on me so that a certain amount of charge $Q$ is transferred from the balloon to my hand, so that the balloon and me have unlike charges on us. The balloon balances under gravity! Determine the charge $Q$.

- The gravitation force on the balloon is nulled by the electrostatic force,

$$mg = \frac{k_e Q^2}{R^2}. \quad (18.4)$$

This leads to $Q = 3.30 \times 10^{-7} \text{ C}$. 

**Lecture-Example 18.3:** A hydrogen atom consists of an electron orbiting a proton. The radius is about $5.3 \times 10^{-11} \text{ m}$. 

- Find the electrostatic force between electron and proton.

$$F_{\text{electric}} = \frac{k_e q_e^2}{R^2} \sim 10^{-8} \text{ N}. \quad (18.5)$$

- Find the gravitational force between electron and proton.

$$F_{\text{gravity}} = \frac{G m_e m_p}{R^2} \sim 10^{-47} \text{ N}. \quad (18.6)$$
18.2. COULOMB’S LAW

- Find the ratio of the electrostatic force to gravitational force. (This is independent of the radius.)

\[
\frac{F_{\text{electric}}}{F_{\text{gravity}}} = \frac{ke^2}{Gm_em_p} \sim 10^{40}. \tag{18.7}
\]

**Lecture-Example 18.4:** Can we detach the Moon?

If charges of same sign are placed on Earth and Moon it could be possible to negate the gravitational force between them. \((m_{\text{Earth}} \sim 6 \times 10^{24} \text{ kg}, m_{\text{Moon}} \sim 7 \times 10^{22} \text{ kg})\) (You do not need the knowledge of the Earth-Moon distance for this calculation, \(R \sim 4 \times 10^8 \text{ m}\).)

- Equating the gravitational force to the electrostatic force we have

\[
\frac{Gm_Em_{\text{moon}}}{R^2} = \frac{kq^2}{R^2} \tag{18.8}
\]

- Thus, the charge needed to release the Moon is \(q = 10^{12} \text{ C}\), which is about 1 kg of electrons. This is a stupendous amount of charge, which when confined to the volume of Earth will breakdown the atmosphere, though not breakdown vacuum!

**Lecture-Example 18.5:** Charges \(q_1 = +3.0 \mu \text{C}\) and \(q_2 = -1.0 \mu \text{C}\) are placed a distance \(x_0 = 10.0 \text{ cm}\) apart. Presume the two charges to be uniformly spread on identical perfectly conducting spheres of radius \(R = 1.0 \text{ cm}\) with masses \(m_1 = 100.0 \text{ g}\) and \(m_2 = 10m_1\).

- Find the forces \(\vec{F}_{12}\) and \(\vec{F}_{21}\) on the charges. Determine the instantaneous accelerations \(\vec{a}_1\) and \(\vec{a}_2\) of spheres when they are \(x_0\) distance apart. (Note that the instantaneous accelerations are not uniform, they are distant dependent and get larger as they get closer.)

Answer: \(a_1 = 27 \text{ m/s}^2\), \(a_2 = 2.7 \text{ m/s}^2\).

- If let go, the two spheres attract, move towards each other, and come in contact. Once in contact, because the charges are on perfectly conducting spheres, the charges will redistribute on the two spheres. Determine the new charges \(q'_1\) and \(q'_2\) on the two spheres to be

\[
q'_1 = q'_2 = \frac{q_1 + q_2}{2}. \tag{18.9}
\]

Answer: \(q'_1 = q'_2 = 1.0 \mu \text{C}\).

- Find the repulsive force on the two spheres after they come into contact. Determine the instantaneous accelerations \(\vec{a}'_1\) and \(\vec{a}'_2\) of the two spheres when they are in contact, their centers a distance \(2R\) apart. Observe that the smaller masses does most of the movement, relatively. (Again, observe that the instantaneous accelerations are not uniform, they are distance dependent and get weaker as they get farther apart.)

Answer: \(a'_1 = 225 \text{ m/s}^2\), \(a'_2 = 22.5 \text{ m/s}^2\).
Lecture-Example 18.6: Where is the force zero?
See Figure 18.2. Two positive charges $q_1$ and $q_2$ are fixed to a line. As a multiple of distance $D$, at what coordinate on the line is the net electrostatic force on a negative charge $q_3$ zero?

\[ x = \frac{D}{1 + \sqrt{\frac{q_2}{q_1}}} \] \hspace{1cm} (18.10)

For $q_2 > q_1$ we have $0 < x < L/2$. And, for $q_2 < q_1$ we have $0 < L/2 < x < L$. In general the equilibrium point is closer to the smaller charge. Investigate if the particle 3 is stable or unstable at this point?

- Repeat the above for a positive charge $q_3$.
- Repeat the above for unlike $q_1$ and $q_2$.

Lecture-Example 18.7:
Fig. 18.3 shows three point charges that lie in the $x$-$y$ plane. Given $q_1 = -4.0 \, \mu\text{C}$, $q_2 = +6.0 \, \mu\text{C}$, $q_3 = +5.0 \, \mu\text{C}$, charges $q_1$ and $q_2$ are separated by a distance of 4.0 cm, and charges $q_1$ and $q_3$ are separated by a distance of 6.0 cm. Find the magnitude and direction of the net electrostatic force on charge $q_1$.

Lecture-Example 18.8: Two positive charges and two negative charges of equal magnitude $q = 3.00 \, \mu\text{C}$ are placed at the corners of a square of length $L = 10$ cm, such that like charges are at diagonally opposite to each other.

- Determine the magnitude of the force on one of the positive charge.
- Analyze the direction of the force on one of the positive charge.
- If the four charges were free to move, will they collectively move away from each other or move towards each other?
18.3 Electric field

Coulomb’s law states that an object with a non-zero charge on it exerts a force on another charge with a non-zero charge. In particular, the Coulomb force does not require the two charges to come in contact. How does one charge know to respond to (say the movement of) another charge? That is, how do they communicate? This was not addressed in Coulomb’s time and this form of interaction between charges is dubbed action-at-a-distance. Since the time of Faraday, in 1830’s, the understanding is that the individual charges are ‘immersed’ in a ‘medium’ termed the electric field. The electric field permeates all space and supplies it with an energy and momentum per unit volume. The electric field associates a vector quantity at every point in space at each time. The presence of an individual charge disturbs the electric field continuum, and another charge responds to this disturbance. Further, our understanding is that these disturbances travel at the speed of light as electromagnetic waves. Our current understanding of gravitational interaction is similar, with the curvature tensor taking the role of electric field.

In terms of the electric field the Coulomb force is effectively the same, but for the fact that it is interpreted as a two stage phenomena: the charge $q_1$ creates an electric field

$$\vec{E}_1 = \frac{kq_1}{r^2} \hat{r}$$

(18.11)

everywhere in space, which exerts a force

$$\vec{F}_{21} = q_2 \vec{E}_1$$

(18.12)
on another charge $q_2$, where $\vec{E}_1$ is the electric field at the position of charge ‘2’, and $\vec{F}_{21}$ is read as the force on ‘2’ due to ‘1’. Conversely, the electric field at a point in space is the force a unit charge would experience if it is placed at the point.

Electric field lines

The electric field associates a vector to every point in space. This information is often represented as electric field lines originating from positive charges and terminating on negative charges. Thus, positive charges are sources of electric field and negative charges are sinks for electric field.

**Lecture-Example 18.9:**
Determine the electric field along the bisector of the line segment connecting two positive charges, $q_1 = q_2 = q$ and distance $2a$. 

![Figure 18.4: Lecture-Example 18.9](image)
The total electric field at a distance $y$ along the bisector is

$$\vec{E}_{\text{tot}} = \vec{E}_1 + \vec{E}_2 = \hat{j} \frac{2kqy}{(y^2 + a^2)^{3/2}}.$$  \hspace{1cm} (18.13)

See Figure 18.4.

- What is the electric force on charge $q_3$ at this point.
- Determine the case for $y \gg a$ and $y \ll a$.

**Lecture-Example 18.10:** (Electric dipole moment)

Two equal and opposite point charges, separated by a distance $d$, have an electric dipole moment given by

$$\vec{p} = q\vec{d},$$  \hspace{1cm} (18.14)

where $\vec{d}$ points from the negative to the positive charge. Determine the electric field along the bisector of an electric dipole.

Figure 18.5: Lecture-Example 18.10

- The total electric field at a distance $y$ along the bisector for $d = 2a$ is

$$\vec{E}_{\text{tot}} = \vec{E}_1 + \vec{E}_2 = -\frac{k\vec{p}}{(y^2 + a^2)^{3/2}}.$$  \hspace{1cm} (18.15)

See Figure 18.5.

- Unless the atoms are ionized, their interaction with other atoms gets significant contributions from the electric dipole moment. Note that, the electric field due to dipoles has an inverse cube dependence in distance, and thus the corresponding force is much weaker than the Coulomb force.
- The electric field along the line joining the charges is significantly weaker. Thus atoms interacting this way would tend to align in a particular way.
- What is the electric force on charge $q_3$ at this point.
- Determine the case for $y \gg a$ and $y \ll a$. Observe that for $y \gg a$ it is very weak, but non-zero.
18.3. ELECTRIC FIELD

Figure 18.6: Lecture-Example 18.11

Lecture-Example 18.11: Figure 18.6 shows four charges, \( q_1 = +1.0 \, \mu\text{C}, \) \( q_2 = +2.0 \, \mu\text{C}, \) \( q_3 = -3.0 \, \mu\text{C}, \) \( q_4 = +2.0 \, \mu\text{C}, \) that are placed on the \( x \) and \( y \) axes. They are all located at the same distance of \( L = 40.0 \, \text{cm} \) from the origin marked as \( \times \). Determine the magnitude and direction of the net electric field at the origin.

Lecture-Example 18.12: Where is the electric field zero?
See Figure 18.7. Two positive charges \( q_1 \) and \( q_2 \) are fixed to a line. As a multiple of distance \( D \), at what coordinate on the line is the electric field zero?

Figure 18.7: Lecture-Example 18.12

- Equate the electric fields to deduce

\[
x = \frac{D}{1 + \sqrt{\frac{q_2}{q_1}}}.
\]  
(18.16)

For \( q_2 > q_1 \) we have \( 0 < x < L/2 \). And, for \( q_2 < q_1 \) we have \( 0 < L/2 < x < L \). In general the zero-point is closer to the smaller charge.

- Repeat the above for unlike \( q_1 \) and \( q_2 \).

Lecture-Example 18.13: (Uniformly charged plate)
Show that the electric field due to a uniformly charged plate with uniform charge density \( \sigma \) is given by

\[
\vec{E} = \hat{r} \frac{\sigma}{2\varepsilon_0},
\]  
(18.17)

where \( \hat{r} \) points away from the plate.

- Determine the surface charge density needed to generate an electric field of 100 N/C? Answer: 1.8 nC/m².
18.4 Motion of a charged particle in a uniform electric field

A charged particle experiences a force in an electric field. If the electric force is the only force acting on the charge the corresponding acceleration is

\[ \vec{a} = \frac{q \vec{E}}{m}. \]  

(18.18)

Observe that, unlike the case of acceleration in a gravitational field, the acceleration in an electric field is mass dependent. That is, a proton will experience an acceleration 2000 times smaller than that experienced by an electron, because a proton is \( \sim 2000 \) times heavier than an electron.

Lecture-Example 18.14:

- Determine the acceleration of a ball of mass \( m = 10.0 \) g with a charge \( q = 1.0 \) \( \mu \)C in an electric field \( E = 1000.0 \) N/C.
  Answer: \( 0.10 \) m/s\(^2\).

- Determine the acceleration of an electron in an electric field \( E = 1000.0 \) N/C.
  Answer: \( 1.8 \times 10^{-14} \) m/s\(^2\).

- Determine the acceleration of a proton in an electric field \( E = 1000.0 \) N/C.
  Answer: \( 9.6 \times 10^{-10} \) m/s\(^2\).

- Starting from rest, determine the distance travelled by the ball, electron, and the proton, in the presence of this electric field in 1 ns.
- Starting from rest, determine the speed attained by the ball, electron, and the proton, in the presence of this electric field in 1 ns.

Lecture-Example 18.15:

A proton is projected horizontally with an initial speed of \( v_i = 1.00 \times 10^5 \) m/s. It enters a uniform electric field with a magnitude of \( E = 100.0 \) N/C pointing vertically down. The electric field is confined between plates with a vertical distance \( y = 2.0 \) cm. Determine the horizontal distance \( x \) the proton moves before it hits the bottom plate.

- The acceleration experienced by the proton in the \( y \) direction due to the electric field is given by
  \[ a_y = \frac{q}{m} E \sim 9.6 \times 10^9 \frac{m}{s^2}. \]  
  (18.19)

  This is very small in comparison to the acceleration due to gravity, \( 9.8 \) m/s\(^2\). Thus, we can neglect the gravitational effects all together in this case.

- The kinematics under this constant acceleration are governed by the equations
  \[ x = v_i t, \]  
  (18.20a)
  \[ y = \frac{1}{2} a_y t^2. \]  
  (18.20b)

  The second equation here lets us evaluate the time it takes for the proton to fall the distance \( y \) as \( t = 2.0 \times 10^{-6} \) s. This in turn lets us evaluate the horizontal distance \( x \) to be 20 cm.

- Repeat the above for an electron. Now we can find \( a_y = 1.7 \times 10^{13} \) m/s\(^2\), which is about 2000 times larger than that of a proton. The time it takes to hit the bottom plate is \( t = 4.9 \times 10^{-8} \) s. This leads to \( x = 4.9 \) mm.

- Repeat this for a metal sphere of mass \( m = 1.0 \) g and charge \( q = 10.0 \) uC. Is it reasonable to neglect gravity in this case?
18.5 Homework problems

**Homework-Problem 18.1:** Four identical metallic objects carry the following charges: $+1.6 \mu\text{C}$, $+6.2 \mu\text{C}$, $-4.8 \mu\text{C}$, and $-9.4 \mu\text{C}$. The objects are brought simultaneously into contact, so that each touches the others. Then they are separated.

1. What is the final charge on each object?

   **Hints:** The final charge $q_f$, on each metallic object is same.

   $$q_f = \frac{\text{Sum of all charges}}{4}.$$  

2. How many electrons (or protons) make up the final charge on each object?

   **Hints:** No hints.

**Homework-Problem 18.2:** Water has a mass per mole of 18.0 g/mol, and each water molecule (H$_2$O) has 10 electrons.

1. How many electrons are there in 1 liter of water? (A liter is $1.00 \times 10^{-3} \text{ m}^3$)

   **Hints:** Find total moles in one liter of water. Then use Avagadro’s number to get total number of water molecules.

   Total number of electrons=10 $\times$ total number of water molecules.

2. What is the net charge of all these electrons?

   **Hints:** No hints.

**Homework-Problem 18.3:** In a vacuum, two particles have charges of $q_1$ and $q_2$, where $q_1 = +3.5 \mu\text{C}$. They are separated by a distance of 0.26 m, and particle 1 experiences an attractive force of 3.4 N. What is $q_2$ (magnitude and sign)?

   **Hints:** Use Coulomb’s law to find magnitude of the charge. For sign use the fact that like charges repel and unlike charges attract each other.

**Homework-Problem 18.4:** Two charges attract each other with a force of 1.2 N. What will be the force if the distance between them is reduced to one-ninth of its original value?

   **Hints:** Use Coulomb’s law and take ratio of two forces.
Homework-Problem 18.5: The drawings show three charges that have the same magnitude but may have different signs. In all cases the distance $d$ between the charges is the same. The magnitude of the charges is $|q| = 8.6 \mu C$, and the distance between them is $d = 3.8 \text{ mm}$. Determine the magnitude of the net force on charge 2 for each of the three drawings.

Hints:
- Use Coulomb’s law to find magnitude of the force on charge 2 due to charge 1 and charge 3: $F_{21}$ and $F_{23}$ respectively.
- Determine the directions of these forces using geometry.
- Use magnitude and direction to write vector form of the two forces: $\vec{F}_{21}$ and $\vec{F}_{23}$.
- Use vector addition $\vec{F}_{\text{net}} = \vec{F}_{21} + \vec{F}_{23}$, to find $x$ and $y$ components of the net force. Find the magnitude of $\vec{F}_{\text{net}}$.

Homework-Problem 18.6: Two tiny spheres have the same mass and carry charges of the same magnitude. The mass of each sphere is $2.0 \times 10^{-6} \text{ kg}$. The gravitational force that each sphere exerts on the other is balanced by the electric force.

1. What algebraic signs can the charges have?

Hints: The gravitational force between two masses is attractive so it will try to pull two spheres together. To balance it the electrostatic force should exert repulsive force.

2. Determine the charge magnitude.

Hints: Equate the Coulomb’s force to the gravitational force. See Interactive LearningWare 18.1 on WebAssign for details.

Homework-Problem 18.7: Three point charges have equal magnitudes, two being positive and one negative. These charges are fixed to the corners of an equilateral triangle, as the drawing shows. The magnitude of each
of the charges is 6.4 C, and the lengths of the sides of the triangle are 5.0 cm. Calculate the magnitude of the net force that each charge experiences.

**Hints:** Use hints from Homework-Problem 18.5.

**Homework-Problem 18.8:** A small spherical insulator of mass 8.00 \times 10^{-2} \text{kg} and charge +0.600 \mu \text{C} is hung by a thread of negligible mass. A charge of −0.900 \mu \text{C} is held 0.150 \text{m} away from the sphere and directly to the right of it, so the thread makes an angle \theta with the vertical (see the drawing).

Find the following.
1. The angle \theta.
2. The tension in the thread.

**Hints:**
- Forces acting on the spherical insulator are the gravitational force \(m \mathbf{g}\), the electrostatic force \(\mathbf{F}_e\), and the tension \(\mathbf{T}\) due to the thread.

\[
m \mathbf{g} + \mathbf{F}_e + \mathbf{T} = m \mathbf{a}.
\]

(18.23)

- Resolve forces in \(x\) and \(y\) directions to obtain

\[
T \cos \theta = mg \quad \text{(18.24a)}
\]

\[
T \sin \theta = F_e. \quad \text{(18.24b)}
\]

- Solve for tension \(T\) and angle \(\theta\).
Homework-Problem 18.9: An electric field of 260,000 N/C points due west at a certain spot. What are the magnitude and direction of the force that acts on a charge of $-6.5 \mu C$ at this spot?

Hints: $\vec{F} = q\vec{E}$

Homework-Problem 18.10: The drawing shows two situations in which charges are placed on the $x$ and $y$ axes. They are all located at the same distance of 6.1 cm from the origin O. For each of the situations in the drawing, determine the magnitude of the net electric field at the origin.

Figure 18.11: Homework-Problem 18.10.

Hints:

- The magnitude of the electric field due to a charge $q$ at a distance $r$ away from the charge is

$$E = \frac{k|q|}{r^2} \quad (18.25)$$

Find magnitude of the electric fields at the origin due to each charge. Determine their directions at the origin by noting that the field lines emerge from a positive charge and converge at a negative charge.

- Write each electric field in vector form.

- Use vector addition $\vec{E}_{\text{net}} = \vec{E}_1 + \vec{E}_2 + \ldots$ to find $x$ and $y$ components of the net electric field using vector addition of the electric fields due to each charge.

- Find the magnitude of $\vec{E}_{\text{net}}$.

Homework-Problem 18.11: A proton and an electron are moving due east in a constant electric field that also points due east. The electric field has a magnitude of $8.0 \times 10^5$ C. Determine the magnitude of the acceleration of the proton and the electron.

Hints:

- Use Newton’s second law ($\vec{F} = m\vec{a}$) and electrostatic force equation ($\vec{F}_e = q\vec{E}$), to deduce

$$\vec{a} = \frac{q}{m} \vec{E}.$$

(18.26)
• Find the magnitude of acceleration. Here \( m \) is the mass of the electron (proton).

**Homework-Problem 18.12:** In Multiple-Concept Example 9 you can use the concepts that are important in this problem. A particle of charge +12 \( \mu \)C and mass \( 3.8 \times 10^{-5} \) kg is released from rest in a region where there is a constant electric field of +480 N/C. What is the displacement of the particle after a time of \( 1.6 \times 10^{-2} \) s?

**Hints:**

• Use hints from Homework-Problem 18.11 to find acceleration acting on the particle.
• Use the relevant kinematic equation to find displacement.
Chapter 19
Gauss’s law

19.1 Scalar product of vectors

The scalar product of two vectors,

\[ \vec{A} = A_x \hat{i} + A_y \hat{j}, \quad (19.1a) \]
\[ \vec{B} = B_x \hat{i} + B_y \hat{j}, \quad (19.1b) \]
\[ \vec{A} \cdot \vec{B} = A_x B_x + A_y B_y. \quad (19.1c) \]

is defined, in terms of the components of the individual vectors, as

\[ \vec{A} \cdot \vec{B} = A_x B_x + A_y B_y. \quad (19.2) \]

In terms of the magnitude and direction of the individual vectors it is equal to

\[ \vec{A} \cdot \vec{B} = |\vec{A}| |\vec{B}| \cos \theta, \quad (19.3) \]

where \( \theta \) here is the angle between the two vectors.

**Lecture-Example 19.1:**

Given \(|\vec{A}| = 1.0, |\vec{B}| = 2.0\), and the angle between the vectors \( \theta = 0^\circ \), show that \( \vec{A} \cdot \vec{B} = 2.0 \).

Given \(|\vec{A}| = 1.0, |\vec{B}| = 2.0\), and the angle between the vectors \( \theta = 30.0^\circ \), show that \( \vec{A} \cdot \vec{B} = 1.7 \).

Given \(|\vec{A}| = 1.0, |\vec{B}| = 2.0\), and the angle between the vectors \( \theta = 60.0^\circ \), show that \( \vec{A} \cdot \vec{B} = 1.0 \).

Given \(|\vec{A}| = 1.0, |\vec{B}| = 2.0\), and the angle between the vectors \( \theta = 90.0^\circ \), show that \( \vec{A} \cdot \vec{B} = 0.0 \).

Given \(|\vec{A}| = 1.0, |\vec{B}| = 2.0\), and the angle between the vectors \( \theta = 135^\circ \), show that \( \vec{A} \cdot \vec{B} = -1.4 \).

Given \(|\vec{A}| = 1.0, |\vec{B}| = 2.0\), and the angle between the vectors \( \theta = 180^\circ \), show that \( \vec{A} \cdot \vec{B} = -2.0 \).

19.2 Electric flux

Flux associated with a field \( \vec{E} \) across a small area \( \Delta A \) is defined as

\[ \Delta \Phi_E = \vec{E} \cdot \Delta \vec{A}. \quad (19.4) \]

Flux associated with a field \( \vec{E} \) across a surface area \( S \) is then given by

\[ \Phi_E = \sum_S \vec{E} \cdot \Delta \vec{A}. \quad (19.5) \]
Electric field lines represent the ‘flow’ of the electric field, and a quantitative measure of this flow across a surface is the electric flux. It is a measure of the number of electric field lines crossing a surface (presuming a fixed number of lines were originating from sources).

Area in our discussions is a vector. Its magnitude is the area of the surface in context, and its direction is normal to the surface. A surface encloses a volume and the normal to the surface is outward with respect to this volume. For an infinite plane, the ambiguity in the sign of the direction of the normal could be removed if we specify which half it is enclosing.

**Lecture-Example 19.2:**
Consider a sheet of paper folded and kept in a uniform electric field \( \mathbf{E} = E_0 \hat{x} \), with \( E_0 = 100.0 \, \text{N/C} \). The vertical side of the area along \( \hat{y} \) is 10.0 cm in length and it is 10.0 cm deep in the \( \hat{z} \) direction. The inclined side has the same height in the \( \hat{y} \) and makes 60.0° with respect to the vertical. Calculate the flux across surface \( S_1 \) and \( S_2 \).

- The flux across surface \( S_1 \) is given by
  \[
  \Phi_{E_S} = E_0 \hat{x} \cdot \hat{x} A_1 = E_0 A_1, \tag{19.6}
  \]
  where we used \( \hat{x} \cdot \hat{x} = 1 \).

- The flux across surface \( S_2 \) is given by
  \[
  \Phi_{E_S} = E_0 \hat{x} \cdot \hat{n} A_2 = E_0 \cos \theta A_2 = E_0 A_1, \tag{19.7}
  \]
  where we used \( \hat{A}_2 = \hat{n} A_2 \), and \( \hat{x} \cdot \hat{n} = \cos \theta \), and \( A_1 = A_2 \cos \theta \).

**Lecture-Example 19.3:**
The drawing shows an edge-on view of a planar surface of area 2.0 m\(^2\). Given \( \theta = 30^\circ \). The electric field vector \( \mathbf{E} \) in the drawing is uniform and has a magnitude of \( 3.0 \times 10^2 \, \text{N/C} \). Determine the electric flux across the planar surface.

![Figure 19.1: Problem 2.](image)

**Lecture-Example 19.4:**
Consider a uniform electric field \( \mathbf{E} = E_0 \hat{x} \). A cube, of edge length \( L = 10.0 \, \text{cm} \), is placed in this electric field with one of the faces perpendicular to the field. Find the electric flux across each of the faces of the cube. Find the total flux across the surface of the cube.
Lecture-Example 19.5:
Flux across a sphere enclosing a point charge at the center.

- Using

\[ \vec{E} = \frac{kQ}{r^2} \hat{r} \quad \text{and} \quad \Delta \vec{A} = \hat{r} \Delta A \]  

the flux is given by

\[ \Phi = \sum_S \vec{E} \cdot \Delta \vec{A} = \frac{kQ}{r^2} \sum_S dA = \frac{kQ}{r^2} 4\pi r^2 = \frac{Q}{\varepsilon_0}. \]  

(19.9)

19.3 Gauss’s law

Gauss’s law states that the electric flux across a closed surface is completely determined by the total charge enclosed inside the surface,

\[ \Phi_E = \sum_S \vec{E} \cdot \Delta \vec{A} = \frac{Q_{en}}{\varepsilon_0}, \]  

(19.10)

where \( Q_{en} \) is the total charge enclosed inside the closed surface \( S \).

Lecture-Example 19.6: (Point charge)
Using the symmetry of a point charge, and presuming the electric field to be radial and isotropic, derive Coulomb’s law using Gauss’s law,

\[ \vec{E} = \frac{kQ}{r^2} \hat{r}. \]  

(19.11)

Lecture-Example 19.7: (Charged spherical shell)
Determine the electric field inside and outside a uniformly charged spherical shell to be

\[ \vec{E} = \begin{cases} \frac{kQ}{r^2} \hat{r}, & R < r, \\ 0, & r < R. \end{cases} \]  

(19.12)

- This suggests that we can not infer about the charge distribution of a sphere based on the measurement of electric field outside the sphere. For example, what can we say about the charge distribution of proton, that is, is it a uniformly charged solid or a shell?

- By analogy, we can conclude that the acceleration due to gravity inside a spherical shell with uniform mass density on the surface will be zero.

Lecture-Example 19.8: (Perfect Conductor of arbitrary shape)
Prove that the electric field inside a conductor of arbitrary shape is exactly zero.

- Inside a conductor is the safest place during lightning.
Lecture-Example 19.9: (Structure of an atom)
The electric field inside and outside a uniformly charged solid sphere of radius $R$ and charge $Q$ is given by

$$\vec{E} = \begin{cases} \frac{kQ}{r^2} \hat{r}, & R < r, \\ \frac{kQr}{R^3} \hat{r}, & r < R. \end{cases} \tag{19.13}$$

- Plot the magnitude of the electric field as a function of $r$.
- Discuss how this contributed to the Rutherford’s model for the structure of atom.

Lecture-Example 19.10:
Consider a perfectly conducting sphere of radius $R = 7.0$ cm with charge $Q = 1.0 \mu$C. Determine the electric flux through the surface of a (Gaussian) sphere of radius 5.0 cm, concentric with respect to the conducting sphere.

19.4 Homework problems

Homework-Problem 19.1: The drawing shows an electron entering the lower left side of a parallel plate capacitor and exiting at the upper right side. The initial speed of the electron is $7.09 \times 10^6$ m/s. The capacitor is $x = 2.41$ cm long, and its plates are separated by $y = 0.193$ cm. Assume that the electric field between the plates is uniform everywhere and find its magnitude.

![Figure 19.2: Homework-Problem 19.1.](image)

Hints: This problem analyzes motion of an electron in 2-dimensions. It is similar to the motion of an object thrown from a cliff with initial horizontal velocity $v_{0x}$. The only difference being: the electron is accelerating due to the uniform electric force acting on it in contrast to the gravity providing the acceleration to the object in the ‘cliff’ problem.

- The final position of the electron $(x, y)$, when it exits from the capacitor, is known. The initial velocity $v_{0x}$ is also known and $v_{0y} = 0$.
- Use Newton’s second law ($\vec{F} = m\vec{a}$) and electrostatic force equation ($\vec{F}_e = q\vec{E}$), to deduce

  $$\vec{a} = \frac{q_e}{m_e} \vec{E}. \tag{19.14}$$

The force due to gravity on an electron is negligible compared to the electrostatic force.
• Notice that the electric force due to the uniform electric field is acting only in the \( y \)-direction. Using this fact to deduce that

\[
a_x = 0 \quad \text{and} \quad a_y = \frac{|q_e|}{m_e} E.
\]  

Here \( E \) is the magnitude of the electric field that we are solving force.

• Use kinematic equations

\[
x = v_{0x} t, \quad \text{(19.16a)}
\]
\[
y = \frac{1}{2} a_y t^2. \quad \text{(19.16b)}
\]

to solve for two unknowns, \( t \) and \( a_y \).

• Use number obtained for \( a_y \) from the previous step in Eq. (19.15) to solve for the magnitude of the electric field \( E \).

Homework-Problem 19.2: A small plastic ball with a mass of \( 6.90 \times 10^{-3} \) kg and with a charge of \( +0.138 \mu \text{C} \) is suspended from an insulating thread and hangs between the plates of a capacitor (see the drawing). The ball is in equilibrium, with the thread making an angle of 30.0\(^\circ\) with respect to the vertical. The area of each plate is 0.0144 m\(^2\). What is the magnitude of the charge on each plate?

Figure 19.3: Homework-Problem 19.2.

Hints:

• Forces acting on the small plastic ball are the gravitational force \( m_b \vec{g} \), the electrostatic force \( \vec{F}_e \), and the tension \( \vec{T} \) due to the thread. (\( m_b \) is the mass of the plastic ball.)

\[
m_b \vec{g} + \vec{F}_e + \vec{T} = m_b \vec{a}. \quad \text{(19.17)}
\]

• Resolve forces in \( x \) and \( y \) directions to obtain

\[
T \cos \theta = m_b g \quad \text{(19.18a)}
\]
\[
T \sin \theta = F_e. \quad \text{(19.18b)}
\]

Solve for \( F_e \).

• Solve for the uniform electric field between the plates using \( F_e = q_b E \). (\( q_b \) is the charge of the plastic ball.)
• Use \( E = \frac{Q_p}{A \varepsilon_0} \) for a parallel plate capacitor to find total charge \( Q_p \) on the plate. \( A \) is the area of the plate, and \( \varepsilon_0 \) is the electric permittivity.

**Homework-Problem 19.3:** A spherical surface completely surrounds a collection of charges. Find the electric flux through the surface if the collection consists of the following charges.

1. a single \(+4.10 \times 10^{-6}\) C charge
2. a single \(-2.00 \times 10^{-6}\) C charge
3. both of the charges in (1) and (2)

**Hints:** Use Gauss’s law, \( \Phi_E = \frac{Q_{\text{encl}}}{\varepsilon_0} \), to find flux in each case. Here \( Q_{\text{encl}} \) is the net charge enclosed inside the surface.

**Homework-Problem 19.4:** The drawing shows an edge-on view of two planar surfaces that intersect and are mutually perpendicular. Surface 1 has an area of 1.5 m\(^2\), while surface 2 has an area of 2.8 m\(^2\). The electric field vector \( \vec{E} \) in the drawing is uniform and has a magnitude of 261 N/C.

![Figure 19.4: Homework-Problem 19.4.](image)

1. Find the electric flux through surface 1.
2. Find the electric flux through surface 2.

**Hints:**

- Determine angle \( \theta \) between the electric field and normal to the respective surface in each case using geometry.
- Use \( \Phi = (E \cos \theta) \Delta A \) to find the electric flux through a surface. (\( \Delta A \) is the area of the surface.)

**Homework-Problem 19.5:** A surface completely surrounds a \(+2.3 \times 10^{-6}\) C charge. Find the electric flux through this surface when the surface is a sphere with a radius of 0.60 m, a sphere with a radius of 0.30 m, and a cube with edges that are 0.30 m long.

**Hints:** Use hints from Homework-Problem 19.3. (Does shape and size of the enclosing surface matter?)
Homework-Problem 19.6: A circular surface with a radius of 0.052 m is exposed to a uniform external electric field of magnitude $1.36 \times 10^4 \text{N/C}$. The electric flux through the surface is 71 $\text{Nm}^2/\text{C}$. What is the angle between the direction of the electric field and the normal to the surface?

Hints: Use $\Phi_E = (E \cos \theta) \Delta A$ to find the angle $\theta$. $\Delta A$ is the area of the circular surface.

Homework-Problem 19.7: A charge $Q$ is located inside a rectangular box. The electric flux through each of the six surfaces of the box is: $\Phi_1 = +1450 \text{Nm}^2/\text{C}$, $\Phi_2 = +2240 \text{Nm}^2/\text{C}$, $\Phi_3 = +4940 \text{Nm}^2/\text{C}$, $\Phi_4 = -1960 \text{Nm}^2/\text{C}$, $\Phi_5 = -3650 \text{Nm}^2/\text{C}$, and $\Phi_6 = -4900 \text{Nm}^2/\text{C}$. What is $Q$?

Hints: Use Gauss’s law

$$\Phi_E = \Phi_1 + \Phi_2 + \Phi_3 + \Phi_4 + \Phi_5 + \Phi_6 = \frac{Q_{\text{encl}}}{\varepsilon_0}.$$  \hspace{1cm} (19.19)

Homework-Problem 19.8: Two spherical shells have a common center. A $-1.9 \times 10^{-6} \text{C}$ charge is spread uniformly over the inner shell, which has a radius of 0.050 m. A $+5.7 \times 10^{-6} \text{C}$ charge is spread uniformly over the outer shell, which has a radius of 0.15 m. Find the magnitude and direction of the electric field a distance (measured from the common center) of (a) 0.20 m, (b) 0.10 m, and (c) 0.025 m.

Hints:

• Draw the inner and the outer shell given in the problem. Draw a spherical Gaussian surface at the distance ($r$) (measured from the common center) asked in the problem (say in part(a)).

• Determine which spherical shells are enclosed inside this Gaussian surface. Thus, determine the net charge enclosed inside the Gaussian surface.

• Use

$$E = \frac{Q_{\text{encl}}}{4\pi r^2 \varepsilon_0}$$  \hspace{1cm} (19.20)

to find the electric field $E$. Magnitude is the absolute value of the number obtained.

• The positive sign indicates that the electric field is pointing outward while the negative sign indicates that the electric field is pointing inwards.

Homework-Problem 19.9: A cube is located with one corner situated at the origin of an $x$, $y$, $z$ coordinate system. One of the cube’s faces lies in the $x$, $y$ plane, another in the $y$, $z$ plane, and another in the $x$, $z$ plane. In other words, the cube is in the first octant of the coordinate system. The edges of the cube are 0.21 m long. A uniform electric field is parallel to the $x$, $y$ plane and points in the direction of the $+y$ axis. The magnitude of the field is 1510 $\text{N/C}$.

1. Using the outward normal for each face of the cube, find the electric flux through each of the six faces. (Let the side of the cube in the $x$, $z$ plane be the bottom of the cube, the side of the cube in the $z$, $y$ plane be the left side of the cube, and the side of the cube in the $x$, $y$ plane be the back of the cube.)

2. Add the six values obtained in the previous part to show that the electric flux through the cubical surface is zero, as Gauss’ law predicts, since there is no net charge within the cube.
Hints:

- Draw figure as described in the problem.
- Find the area ($\Delta A$) of one face of the cube. Determine the angle $\theta$ between the uniform electric field pointing in $+y$ direction and the outward normal of respective faces of the cube. Notice that angle $\theta$ will be different for different faces of the cube.
- Use $\Phi_E = (E \cos \theta) \Delta A$ to find flux through respective faces.
- Second part is self-explanatory.
Chapter 20

Electric potential energy and the electric potential

20.1 Work done by the electric force

The electric force on a charge $q$ in an electric field $\vec{E}$ is given by

$$\vec{F} = q\vec{E}. \quad (20.1)$$

The work done by the electric force on charge $q$ is given by

$$W = \vec{F} \cdot \vec{d} = Fd\cos\theta = qEd\cos\theta, \quad (20.2)$$

where $\vec{d}$ is the displacement and $\theta$ is the angle between the force and displacement.

**Lecture-Example 20.1:** Consider a region of uniform electric field $\vec{E} = -E\hat{j}$ of magnitude $E = 1.0 \times 10^3 \text{ N/C}$ and direction vertically down. Determine the work done by the electric force when a charged sphere with charge $q = 10.0 \mu\text{C}$ is moved along a path. Let the vertical distance between points ‘1’ to ‘2’ be $h = 10.0 \text{ cm}$.

- The work done by the electric force when the particle moves along the path connecting points ‘1’ to ‘2’, ‘2’ to ‘3’, and ‘3’ to ‘1’, are

$$W_{1\to2} = -qEh, \quad (20.3a)$$

$$W_{2\to3} = 0, \quad (20.3b)$$

$$W_{3\to1} = qEh. \quad (20.3c)$$

425
Further, the total work done by the electric force for the closed loop 1 → 2 → 3 → 1 is

\[ W_{1 \to 2 \to 3 \to 1} = 0. \]  \hspace{1cm} (20.4)

Note that the work done is zero for a path that is perpendicular to the electric field. An arbitrary path can be broken down into infinitely small vertical and horizontal displacements. Thus, for the case of uniform electric field we can show that the work done is independent of the path and only depends on the initial and final points.

20.2 Electric potential energy

The work done by the electric force is zero for a closed path (in the absence of time varying magnetic fields). As a corollary, the work done by the electric force is completely determined by the initial and final points of the path traversed. This is the statement of the electric force being a conservative force. For a conservative force it is convenient to define an associated potential energy, in the statement of work-energy theorem. The electric potential energy of a charge \( q \) in a uniform electric field created in between oppositely charged parallel plates, choosing the potential energy to be zero when the charge is at the negative plate, is

\[ U = qEh, \]  \hspace{1cm} (20.5)

\( h \) being the distance of the charge from the negative plate. The electric potential energy of two charges \( q_1 \) and \( q_2 \), choosing the potential energy to be zero at infinity, is

\[ U = \frac{kq_1 q_2}{r}. \]  \hspace{1cm} (20.6)

**Lecture-Example 20.2:** (Point charges)

A positive charge \( q_2 \) is moved in the vicinity of another positive charge \( q_1 \). Determine the work done by the electric force when the charge \( q_2 \) is moved along a path.

- Evaluate the work done by the electric force on the charge \( q_2 \) when it is moved along the path ‘1’ to ‘2’, ‘2’ to ‘3’, ‘3’ to ‘4’, ‘4’ to ‘1’.
- Plot the electric potential energy \( U \) between two positive charges \( q_1 \) and \( q_2 \) as a function of \( r \). Next, plot the electric potential energy \( U \) between two unlike charges \( q_1 \) and \( q_2 \) as a function of \( r \). Interpret these plots as a statement of the fact that force is the manifestation of the system trying to minimize its energy.
20.2. ELECTRIC POTENTIAL ENERGY

- Equipotential surfaces are surfaces perpendicular to the electric field. The work done by the electric force is zero while moving on equipotential surfaces.

Lecture-Example 20.3: (Energy required to assemble a set of charges)
Show that the energy required to assemble three positive charges \( q_1, q_2, \) and \( q_3, \) at relative distances \( r_{12}, r_{23}, \) and \( r_{31}, \) is

\[
U = \frac{kq_1q_2}{r_{12}} + \frac{kq_2q_3}{r_{23}} + \frac{kq_3q_1}{r_{31}}. \tag{20.7}
\]

- Show that the total energy required to assemble three identical positive charges \( q \) at the corners of an equilateral triangle of side \( L \) is

\[
U = 3 \frac{kq^2}{L}. \tag{20.8}
\]

- Show that the total energy required to assemble four identical positive charges \( q \) at the corners of a square of side \( L \) is

\[
U = (4 + \sqrt{2}) \frac{kq^2}{L}. \tag{20.9}
\]

Lecture-Example 20.4:
A sphere with mass \( m_2 = 10 \text{ g} \) and charge \( q_2 = 1.0 \mu\text{C} \) is fired directly toward another sphere of charge \( q_1 = 10.0 \mu\text{C} \) (which is pinned down to avoid its motion). If the initial velocity of charge \( q_2 \) is \( v_i = 10.0 \text{ m/s} \) when it is \( r_i = 30 \text{ cm} \) away from charge \( q_1, \) at what distance away from the charge \( q_1 \) does it come to rest?

- Using conservation of energy we have

\[
\frac{kq_1q_2}{r_i} + \frac{1}{2}m_2v_i^2 = \frac{kq_1q_2}{r_f} + \frac{1}{2}m_2v_f^2. \tag{20.10}
\]

Answer: \( r_f = 11 \text{ cm}. \)

Lecture-Example 20.5:
Two oppositely charged, parallel plates are placed \( d = 8.0 \text{ cm} \) apart to produce an electric field of strength \( E = 1.0 \times 10^3 \text{ N/C} \) between the plates. A sphere of mass \( m = 10.0 \text{ g} \) and charge \( q = 10.0 \mu\text{C} \) is projected from one surface directly toward the second. What is the initial speed of the sphere if it comes to rest just at the second surface?

- Using conservation of energy we have

\[
\frac{1}{2}mv^2 = qEd. \tag{20.11}
\]

Answer: \( v = 0.4 \text{ m/s}. \)
20.3 Electric potential

Electric potential energy per unit charge is defined as the electric potential. It is measured in units of Volt=Joule/Coulomb. Thus,

\[ \Delta U = q\Delta V. \]  \hspace{1cm} (20.12)

For a point charge, after choosing the electric potential to be zero at infinity, we have

\[ V = \frac{kq}{r}. \]  \hspace{1cm} (20.13)

For uniform electric field created by oppositely charged parallel plates, after choosing the electric potential to be zero at the negative plate, we have

\[ V = Eh, \]  \hspace{1cm} (20.14)

\( h \) being the distance from the negative plate.

Lecture-Example 20.6:
Two electrons and two protons are placed at the corners of a square of side 5 cm, such that the electrons are at diagonally opposite corners.

- What is the electric potential at the center of square?
- What is the electric potential at the midpoint of either one of the sides of the square?
- How much potential energy is required to move another proton from infinity to the center of the square?
- How much additional potential energy is required to move the proton from the center of the square to one of the midpoint of either one of the sides of the square?

Lecture-Example 20.7:
Charges of \(-q\) and \(+2q\) are fixed in place, with a distance of \(a = 2.0 \text{ m}\) between them. See Fig. 20.3. A dashed line is drawn through the negative charge, perpendicular to the line between the charges.

- On the dashed line, at a distance \(y\) from the negative charge, there is at least one spot where the total potential is zero. Find \(y\). (Answer: \(y = \pm a/\sqrt{3}\).)
- On the line connecting the charges, between the two charges, find the spot where the total potential is zero. (Answer: Distance \(a/3\) to the right of \(-q\) charge.) On the line connecting the charges, to the left of the smaller charge, find the spot where the total potential is zero. (Answer: Distance \(a\) to the left of \(-q\) charge.)
• On the line connecting the charges, to the right of the larger charge, show that there is no spot where the total potential is zero. In general for \( \alpha = q_2/q_1 < 0 \), remembering that the potential involves the magnitude of the distance, the two solutions on the line connecting the charges are contained as solutions to the quadratic equation,

\[
(\alpha^2 - 1)z^2 + 2az - a^2 = 0,
\]

which has solutions

\[
z = \frac{a}{1 + \alpha} \quad \text{and} \quad z = \frac{a}{1 - \alpha}. \tag{20.15}
\]

• For like charges, \( \alpha = q_2/q_1 > 0 \), there is no spot with zero potential other than infinity, because two positive numbers can not add to give zero.

20.4 Electric potential inside a perfectly charged conductor

Since the electric field is zero inside a perfectly charged conductor, because otherwise the charges will experience a force, the implication is that the electric potential is a constant inside the conductor.

Lecture-Example 20.8:
Determine the electric potential inside and outside a perfectly conducting charged sphere of radius \( R \). Plot this.

Lecture-Example 20.9: (Fork in a microwave)
To illustrate why pointed metals spark inside a microwave, let us consider two conducting spheres of radius \( R_1 \) and \( R_2 \), connected by a conducting thread, but placed significantly away from each other.

• Using the fact that the electric potential is the same at the surface of the two spheres,

\[
V_1 = V_2, \tag{20.17}
\]

show that the ratio of the charges on the two spheres is

\[
\frac{Q_1}{Q_2} = \frac{R_1}{R_2}. \tag{20.18}
\]

Thus, the charge is proportional to the radius.

• Show that the ratio of the electric fields is

\[
\frac{E_1}{E_2} = \frac{R_2}{R_1}. \tag{20.19}
\]

Thus, the electric field is inversely proportional to the radius. This implies the smaller sphere will have a larger electric field near its surface. If the electric field is large enough to breakdown air, we see a spark.
20.5 Capacitor

The potential difference between two conducting objects, consisting of equal and opposite charge $Q$, is linearly dependent on the charge $Q$ and the geometrical dependence on the shape of the objects can be absorbed into a constant. In general, we have

$$V = \frac{Q}{C},$$

(20.20)

where the electric potential is chosen to be zero at the negative plate. The geometry dependent parameter $C$ is defined as the capacitance. For parallel plate configuration the capacitance is given by

$$C = \frac{\varepsilon_0 A}{d},$$

(20.21)

where $A$ is the area of the individual plates and $d$ is the distance between the plates.

The total energy stored in a capacitor is given by

$$U = \frac{Q^2}{2C} = \frac{1}{2} CV^2,$$

(20.22)

which is also the energy required to separate the charges. This energy is stored as the electric field in between the plates,

$$\frac{U}{Ad} = \frac{1}{2} \varepsilon_0 E^2.$$  

(20.23)

Lecture-Example 20.10: (A rudimentary capacitor)
Cut out two strips of aluminum foil, $A = 1 \text{ cm} \times 1 \text{ m} = 10^{-2} \text{ m}^2$. Place a sheet of paper in between the strips and roll the sheets. Estimate the thickness of paper to be $d = 100 \mu \text{m}$. The medium between the plates is paper, which has a permittivity of $\varepsilon \sim 3.9 \varepsilon_0$. Estimate the capacitance of this construction. (Answer: $C \sim 1 \text{nF}$.)

- Traditional capacitors used in electrical circuits range between picofarad (pF) and microfarad ($\mu$F). Parasitic capacitance, the unavoidable stray capacitance, is typically about 0.1 pF. More recently, capacitance greater than kilofarad (kF) have been feasible, and are called supercapacitors.

Lecture-Example 20.11:
The breakdown field strength of paper is about ten times that of air, $E_c \sim 10^7 \text{ V/m}$. Determine the maximum energy that can be stored in the rudimentary capacitor of Lecture-Example 20.10. (Answer: $\sim 1 \text{ mJ}$.)

20.6 Homework problems

Homework-Problem 20.1: A particle has a charge of $+1.5 \mu \text{C}$ and moves from point A to point B, a distance of 0.17 m. The particle experiences a constant electric force, and its motion is along the line of action of the force. The difference between the particle’s electric potential energy at A and B is $E_{PE_A} - E_{PE_B} = +8.50 \times 10^{-4} \text{ J}$.

1. Find the magnitude and direction of the electric force that acts on the particle.
2. Find the magnitude and direction of the electric field that the particle experiences.

Hints:
20.6. HOMEWORK PROBLEMS

- The difference between the particle’s electric potential energy at A and B equals the work done by the electric force acting on the particle,

\[ \text{EPE}_A - \text{EPE}_B = W_{AB} = F_e d \cos \theta, \quad (20.24) \]

where \( \theta \) is the angle between the direction of the constant electric force and the direction of the motion of the particle. Note that particle’s motion is along the line of action of the force.

Use above equation to solve for \( F_e \).

- Use \( \vec{E} = \vec{F}_e / q \) to solve for the electric field.

Homework-Problem 20.2: In a television picture tube, electrons strike the screen after being accelerated from rest through a potential difference of 19100 V. The speeds of the electrons are quite large, and for accurate calculations of the speeds, the effects of special relativity must be taken into account. Ignoring such effects, find the electron speed just before the electron strikes the screen.

Hints: Use conservation of energy

\[ \frac{1}{2} m v_B^2 + \text{EPE}_B = \frac{1}{2} m v_A^2 + \text{EPE}_A \quad (20.25) \]

and the electric potential difference

\[ \text{EPE}_A - \text{EPE}_B = q(V_A - V_B), \quad (20.26) \]

to find \( v_B \).

Note that electron’s velocity at point A is zero.

See Chapter 19, Example 4 for details of modeling of the problem.

Homework-Problem 20.3: An electron and a proton, starting from rest, are accelerated through an electric potential difference of the same magnitude. In the process, the electron acquires a speed \( v_e \), while the proton acquires a speed \( v_p \). Find the ratio \( v_e / v_p \).

Hints: This problem is closely related to the previous problem.

- Use conservation of energy

\[ \frac{1}{2} m v_B^2 + \text{EPE}_B = \frac{1}{2} m v_A^2 + \text{EPE}_A \quad (20.27) \]

to find algebraic expression for electron speed and proton speed at point B. Use definition of the electric potential difference to replace the electric potential energy difference. Mass and charge will be different in two cases.

- Take ratio and note that \( V_A - V_B = \Delta V_{AB} \) will cancel out.

Homework-Problem 20.4: The drawing shows a square, each side of which has a length of \( L = 0.25 \) m. Two different positive charges \( q_1 \) and \( q_2 \) are fixed at the corners of the square. Find the electric potential energy of a third charge \( q_3 = -3.80 \times 10^{-8} \) C placed at corner A and then at corner B.
Hints: The electric potential energy of the third charge \( q_3 \) at point A due to charges \( q_1 \) and \( q_2 \) is

\[
E_{PE,A} = q_3(V_1 + V_2),
\]

where \( V_1 \) and \( V_2 \) are the potential at point A due to charge \( q_1 \) and \( q_2 \), respectively. Repeat for point B.

See Chapter 19, Example 8 for details.

Homework-Problem 20.5: Charges of \(-q\) and \(+2q\) are fixed in place, with a distance of 2.61 m between them. A dashed line is drawn through the negative charge, perpendicular to the line between the charges. On the dashed line, at a distance \( L \) from the negative charge, there is at least one spot where the total potential is zero. Find \( L \).

Hints:

- Total potential at certain location(O) is zero, which implies

\[
\frac{kq_1}{r_1} + \frac{kq_2}{r_2} = 0.
\]

Here \( q_1 \) and \( q_2 \) are the given charges and \( r_1 \) and \( r_2 \) are their respective distances from the location (O).

- Determine \( r_1 \) and \( r_2 \) using geometry.

- Plug it back in the equation and solve for \( L \).
20.6. HOMEWORK PROBLEMS

Homework-Problem 20.6: Determine the electric potential energy for the array of three charges in the drawing, relative to its value when the charges are infinitely far away and infinitely far apart. (Let \( q_1 = 8.16 \mu C \), \( q_2 = 18.0 \mu C \), and \( q_3 = -15.7 \mu C \).)

Hints: See Chapter 19, Example 8.

Homework-Problem 20.7: An electron is released from rest at the negative plate of a parallel plate capacitor and accelerates to the positive plate (see the drawing). The plates are separated by a distance of 1.8 cm, and the electric field within the capacitor has a magnitude of \( 2.8 \times 10^6 \) V/m. What is the kinetic energy of the electron just as it reaches the positive plate?

Hints:
- Find the potential difference between positive and negative plate of the capacitor using \( E = -\Delta V/\Delta s \).
- Find work done by the capacitor in moving electron from the negative plate to the positive plate using \( W = -q\Delta V \).
- Use work-energy relation, \( W = \Delta K \), to find the change in kinetic energy (\( \Delta K \)).

Homework-Problem 20.8: What is the capacitance of a capacitor that stores 3.9 \( \mu C \) of charge on its plates when a voltage of 1.6 V is applied between them?
Homework-Problem 20.9: Two identical capacitors store different amounts of energy: capacitor A stores $3.2 \times 10^{-3}$ J, and capacitor B stores $4.2 \times 10^{-4}$ J. The voltage across the plates of capacitor B is 11 V. Find the voltage across the plates of capacitor A.

**Hints:** Write expression for energy stored by capacitors using $E = \frac{1}{2}CV^2$ for the two cases. Use the fact that two identical capacitors have same capacitance, $C$. 

Chapter 21

Electric circuits

We have learned that positive charges tend to move from a point of higher electrical potential to a point of lower electrical potential, and negative charges tend to do the opposite. This basic idea is at the heart of electrical circuits, which involves flow of electric charges. A traditional battery is a device that provides a (constant) potential difference, by moving charges against their natural tendency. The three basic electrical components will will discuss are: capacitor, resistor, and inductor.

21.1 Current

Flow of electric charges (in a conducting wire) is described by current,

\[ I = \frac{\Delta q}{\Delta t}. \]  

(21.1)

It is measured in units of Ampère=Coulomb/second. It is expressed in terms of the number density of charge carriers \( n \), area of crosssection of the wire \( A \), and drift velocity (speed of flow) \( v_d \), as

\[ I = neAv_d. \]  

(21.2)

**Lecture-Example 21.1:** (Drift velocity)

Estimate the drift velocity in typical metals. Let us consider a current of \( I = 1 \) A passing through a copper wire with area of crosssection \( A = \pi r^2 = \pi (1 \text{ mm})^2 \sim 3 \times 10^{-6} \text{ m}^2 \). Since Copper has one free electron per atom, density of 8.9 g/cm³, and atomic weight of 63.5 g/mole, we estimate \( n = 9 \times 10^{28} \) atoms/m³. (Avagadro’s number is \( 6 \times 10^{23} \) atoms/mole.) (Answer: \( v_d = 2 \times 10^{-5} \) m/s.)

- How much time does it take for an individual electron to begin from the light switch to the bulb that is connected by a 2 m copper wire? (Answer: 28 hours.)

- To put on the light switch it is the flow that is relevant, very much like water arriving at the faucet instantly.

21.2 Resistance

Resistance in a wire is the opposition to the flow of charges. For standard materials it is proportional to the length of wire \( l \), inversely proportional to area of crosssection \( A \), in addition to it depending on the material specific property, the resistivity \( \rho \). Together, we have

\[ R = \frac{\rho l}{A}. \]  

(21.3)
CHAPTER 21. ELECTRIC CIRCUITS

It is measured in units of Ohms=Volt/Ampère.

21.3 Ohm’s law

The current $I$ flowing through a resistor $R$ is directly proportional to the potential difference across the resistor, for many materials. This is the statement of Ohm’s law,

$$V = IR.$$  \hspace{1cm} (21.4)

21.4 Power dissipated in a resistor

The power dissipated in a resistor is given by

$$P = IV = \frac{V^2}{R} = I^2R.$$  \hspace{1cm} (21.5)

21.5 Resistors in series and parallel

A resistor when connected to a battery leads to a flow of current. The current $I$ is decided by the resistance $R$ and potential difference $V$ across the resistor,

$$I = \frac{V}{R}.$$  \hspace{1cm} (21.6)

Lecture-Example 21.2:

A resistor $R = 500 \, \Omega$ is connected across a $10.0 \, \text{V}$ battery. Determine the current in the circuit. (Answer: $20 \, \text{mA}$.)

Resistors in series

Consider two resistors in series as described in Figure 21.1. Since the potential difference across the battery is distributed across the two resistors we deduce that

$$V = V_1 + V_2.$$  \hspace{1cm} (21.7)

The current flowing both the resistors is the same,

$$I_1 = I_2,$$  \hspace{1cm} (21.8)

because the channel for flow does not bifurcate. An equivalent resistor $R_{eq}$ shown on the right side in Figure 21.1 is defined as a resistor that will pull the same amount of current from the battery. Thus, using $V_1 = I_1R_1$, $V_2 = I_2R_2$, and $V = I_{eq}R_{eq}$, in Eq. (21.7), we learn that

$$R_{eq} = R_1 + R_2.$$  \hspace{1cm} (21.9)

We can further deduce that

$$\frac{V_1}{V_2} = \frac{R_1}{R_2},$$  \hspace{1cm} (21.10)

which turns out to be handy in the analysis of more complicated configurations.

Lecture-Example 21.3: (Resistors in series)

A potential difference $V = 10.0 \, \text{V}$ is applied across a resistor arrangement with two resistances connected in series, $R_1 = 100.0 \, \Omega$ and $R_2 = 200.0 \, \Omega$. 
21.5. RESISTORS IN SERIES AND PARALLEL

![Resistors in series](image1)

- Find the equivalent capacitance. (Answer: $R_{eq} = 300.0 \, \Omega$.)
- Find the currents $I_1$ and $I_2$ flowing through the resistors. (Answer: $I_1 = I_2 = 33.3 \, mA$.)
- Find the voltages $V_1$ and $V_2$ across each of the resistors. (Answer: $V_1 = 3.33 \, V$ and $V_2 = 6.67 \, V$.)
- Find the power $P_1$ and $P_2$ dissipated in each of the resistors. (Answer: $P_1 = 111 \, mW$ and $P_2 = 222 \, mW$.)

Resistors in parallel

Consider two resistors in parallel as described in Figure 21.2. The potential difference across each resistor is identical,

$$V = V_1 = V_2. \quad (21.11)$$

The total current $I$ that flows out of the battery distributes between the two resistors,

$$I = I_1 + I_2. \quad (21.12)$$

An equivalent resistor $R_{eq}$ shown on the right side in Figure 21.2 is defined as a resistor that will pull the same amount of current from the battery. Thus, using $I_1 = V_1/R_1$, $I_2 = V_2/R_2$, and $I = V/R_{eq}$, in Eq. (21.12), we learn that

$$\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2}. \quad (21.13)$$

We can further deduce that

$$\frac{I_1}{I_2} = \frac{R_2}{R_1}, \quad (21.14)$$

which turns out to be handy in the analysis of more complicated configurations.

![Resistors in parallel](image2)

Lecture-Example 21.4: (Resistors in parallel)

A potential difference $V = 10.0 \, V$ is applied across a resistor arrangement with two resistances connected in parallel, $R_1 = 100.0 \, \Omega$ and $R_2 = 200.0 \, \Omega$. 
• Find the equivalent resistance. (Answer: $R_{eq} = 66.7 \, \Omega$.)
• Find the voltages $V_1$ and $V_2$ across each of the resistors. (Answer: $V_1 = V_2 = 10.0 \, \text{V}$.)
• Find the currents $I_1$ and $I_2$ flowing through each of the resistors. (Answer: $I_1 = 100 \, \text{mA}$ and $I_2 = 50 \, \text{mA}$.)
• Find the power $P_1$ and $P_2$ dissipated in each of the resistors. (Answer: $P_1 = 1.00 \, \text{W}$ and $P_2 = 0.500 \, \text{W}$.)

### 21.6 Capacitors in series and parallel

A capacitor when connected to a battery collects equal and opposite charges on its plates. The amount of charge $Q$ it collects is decided by the capacitance $C$ and potential difference $V$ across the plates,

$$Q = CV.$$  \hspace{1cm} (21.15)

**Lecture-Example 21.5:**

A capacitor of capacitance $C = 10 \, \mu\text{F}$ is connected across a 10.0 V battery. Determine the charge accumulated on the plates of the capacitor. (Answer: 100 $\mu\text{C}$.)

**Capacitors in series**

Consider two capacitors in series as described in Figure 21.3. Since the potential difference across the battery is distributed across the two capacitors we deduce that

$$V = V_1 + V_2.$$  \hspace{1cm} (21.16)

The charges on each of the capacitors will be identical,

$$Q_1 = Q_2,$$  \hspace{1cm} (21.17)

because by construction the part of circuit between the two capacitors is isolated. An equivalent capacitor $C_{eq}$ shown on the right side in Figure 21.3 is defined as a capacitor that will collect the same amount of charge from the battery. Thus, using $V_1 = Q_1/C_1$, $V_2 = Q_2/C_2$, and $V = Q_{eq}/C_{eq}$, in Eq. (21.16), we learn that

$$\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2}.$$  \hspace{1cm} (21.18)

We can further deduce that

$$\frac{V_1}{V_2} = \frac{C_2}{C_1},$$  \hspace{1cm} (21.19)

which turns out to be handy in the analysis of more complicated configurations.

**Lecture-Example 21.6:** (Capacitors in series)

A potential difference $V = 10.0 \, \text{V}$ is applied across a capacitor arrangement with two capacitances connected in series, $C_1 = 10.0 \, \mu\text{F}$ and $C_2 = 20.0 \, \mu\text{F}$.

- Find the equivalent capacitance. (Answer: $C_{eq} = 6.67 \, \mu\text{F}$.)
- Find the charges $Q_1$ and $Q_2$ on each of the capacitors. (Answer: $Q_1 = Q_2 = 66.7 \, \mu\text{C}$.)
- Find the voltages $V_1$ and $V_2$ across each of the capacitors. (Answer: $V_1 = 6.67 \, \text{V}$ and $V_2 = 3.33 \, \text{V}$.)
- Find the potential energies $U_1$ and $U_2$ stored inside each of the capacitors. (Answer: $U_1 = 222 \, \mu\text{J}$ and $U_2 = 111 \, \mu\text{J}$.)
21.6. CAPACITORS IN SERIES AND PARALLEL

Consider two capacitors in parallel as described in Figure 21.4. The potential difference across each capacitor is identical,
\[ V = V_1 = V_2. \]  
(21.20)
The total charge \( Q \) that is pulled out of the battery distributes on the two capacitors,
\[ Q = Q_1 + Q_2. \]  
(21.21)
An equivalent capacitor \( C_{eq} \) shown on the right side in Figure 21.4 is defined as a capacitor that will collect the same amount of charge from the battery. Thus, using \( Q_1 = V_1 C_1 \), \( Q_2 = V_2 C_2 \), and \( Q = V C_{eq} \), in Eq. (21.21), we learn that
\[ C_{eq} = C_1 + C_2. \]  
(21.22)
We can further deduce that
\[ \frac{Q_1}{Q_2} = \frac{C_1}{C_2}, \]  
(21.23)
which turns out to be handy in the analysis of more complicated configurations.

Lecture-Example 21.7: (Capacitors in parallel)
A potential difference \( V = 10.0 \text{ V} \) is applied across a capacitor arrangement with two capacitances connected in parallel, \( C_1 = 10.0 \mu \text{F} \) and \( C_2 = 20.0 \mu \text{F} \).

- Find the equivalent capacitance. (Answer: \( C_{eq} = 10.0 \mu \text{F} \).)
- Find the voltages \( V_1 \) and \( V_2 \) across each of the capacitors. (Answer: \( V_1 = V_2 = 10.0 \text{ V} \).)
- Find the charges \( Q_1 \) and \( Q_2 \) on each of the capacitors. (Answer: \( Q_1 = 0.100 \text{ mC} \) and \( Q_2 = 0.200 \text{ mC} \).)
- Find the potential energies \( U_1 \) and \( U_2 \) stored inside each of the capacitors. (Answer: \( U_1 = 0.500 \text{ mJ} \) and \( U_2 = 1.00 \text{ mJ} \).)
21.7 Homework problems

**Homework-Problem 21.1:** An especially violent lightning bolt has an average current of $1.28 \times 10^3$ A lasting 0.143 s. How much charge is delivered to the ground by the lightning bolt?

**Hints:** Use $\Delta q = I \Delta t$.

**Homework-Problem 21.2:** The resistance of a bagel toaster is $13 \, \Omega$. To prepare a bagel, the toaster is operated for one minute from a 120 V outlet. How much energy is delivered to the toaster?

**Hints:**
- Find amount of charge flowing through the bagel toaster using $\Delta q = I \Delta t$, where $I = V/R$ is the current in the circuit.
- Energy: $E = V \Delta q$.

**Homework-Problem 21.3:** The resistance and the magnitude of the current depend on the path that the current takes. The drawing shows three situations in which the current takes different paths through a piece of material. Each of the rectangular pieces is made from a material whose resistivity is $\rho = 1.50 \times 10^{-2} \, \Omega \cdot m$, and the unit of length in the drawing is $L_0 = 4.00 \, \text{cm}$. Each piece of material is connected to a 3.00 V battery. Find (a) the resistance and (b) the current in each case.

![Figure 21.5: Homework-Problem 21.3.](image)

**Hints:**
- We need 
  \[ R = \rho \frac{L}{A} \]  
  (21.24) 
  to find resistance, where $\rho$ is the resistivity, $L$ is the length, and $A$ is the cross-sectional area of the material.
- Identify the length $L$ and cross-sectional area $A$ for each case.
- Use Ohm’s law, $I = V/R$, to find current.
Homework-Problem 21.4: The heating element in an iron has a resistance of 27 $\Omega$. The iron is plugged into a 120 V outlet. What is the power delivered to the iron?

Homework-Problem 21.5: A piece of Nichrome wire has a radius of $6.50 \times 10^{-4}$ m. It is used in a laboratory to make a heater that uses $2.00 \times 10^2$ W of power when connected to a voltage source of 120 V. Ignoring the effect of temperature on resistance, estimate the necessary length of wire.

Hints:
- Power and voltage are given. Find resistance using electric power, $P = V^2/R$.
- The Nichrome wire has cross-sectional area $A = \pi r^2$, where $r$ is the radius.
- Use
  $R = \frac{\rho L}{A}$  \hspace{1cm} (21.25)
  and solve for length $L$ needed. Look up the resistivity, $\rho$, for Nichrome.

Homework-Problem 21.6: A 75.0 W lamp is placed in series with a resistor and a 120.0 V source. If the voltage across the lamp is 30 V, what is the resistance $R$ of the resistor?

Hints:
- For series circuit, Source voltage = voltage across lamp($V_L$) + Voltage across resistor($V_R$).
- Lamp and resistor are in series, therefore same current ($I$) flows through both of them. Find current using power given for the lamp: $P = I V_L$.
- Use Ohm’s law, $V_R = I R$, to solve for the resistance.

Homework-Problem 21.7: The drawing shows three different resistors in two different circuits. The battery has a voltage of $V = 24.1$ V, and the resistors have resistances of $R_1 = 50.0 \Omega$, $R_2 = 25.0 \Omega$ and $R_3 = 10.0 \Omega$. Determine the current through and the voltage across each resistor.

Hints:
- For series circuit same current flows through each resistor but voltage across each resistor is different.
- Equivalent resistance, $R_S$, for the series circuit is
  $R_S = R_1 + R_2 + R_3$.  \hspace{1cm} (21.26)
- Use Ohm’s law, $I_S = V/R_S$, to find current drawn from battery.
- Use Ohm’s law, $V_i = I_S R_i$, where $i = 1, 2, 3$, to find voltage across each resistor.
For parallel circuit the voltage across each resistor is same but the current flowing through each resistor is different. Use Ohm’s law, \( I = V/R_i \), where \( i = 1, 2, 3 \), to find current across each resistor.

**Homework-Problem 21.8:** The drawing shows a circuit that contains a battery, two resistors, and a switch. Consider the circuit with \( R_1 = 66.9 \, \Omega \), \( R_2 = 88.2 \, \Omega \), and \( V = 9.1 \, V \).

![Figure 21.7: Homework-Problem 21.8.](image)

**Hints:**
- When switch is open it is a series circuit with single resistance, \( R_1 \), which is the equivalent resistance for this circuit.
- When switch is closed it is a parallel circuit. Use

\[
\frac{1}{R_P} = \frac{1}{R_1} + \frac{1}{R_2}
\]

(21.27)

to find equivalent resistance \( R_P \).
- Use \( P = V^2/R \) to find total power delivered to the resistors. Here \( R \) is the equivalent resistance in the respective cases.

**Homework-Problem 21.9:** For the combination of resistors shown in the drawing (\( R_1 = 78 \, \Omega \), \( R_2 = 65 \, \Omega \)), determine the equivalent resistance between points A and B.

**Hints:** First find equivalent resistance for the two resistances in parallel. Add it to the resistor in series to find total equivalent resistance.
**Homework-Problem 21.10:** Three capacitors are connected in series. The equivalent capacitance of this combination is $2.85 \mu F$. Two of the individual capacitances are $5.52 \mu F$ and $8.55 \mu F$. What is the third capacitance (in $\mu F$)?

**Hints:** Use relation for the equivalent capacitance for a circuit for three capacitors

$$\frac{1}{C_S} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} \quad (21.28)$$

to solve for $C_3$.

**Homework-Problem 21.11:** Determine the equivalent capacitance between A and B for the group of capacitors in the drawing. Let $C_1 = 11 \mu F$ and $C_2 = 4.0 \mu F$.

**Hints:** Problem requires use of series and parallel equivalent capacitance expression few times. *(Drawing a circuit diagram at each step will help.)*

- Start from the right most three capacitors in series to find their equivalent capacitance. This equivalent capacitance will be in parallel to the middle *(vertical)* capacitor.
- Now use parallel equivalent capacitance expression to get equivalent capacitance for these two parallel capacitances. The new equivalent capacitance is now in series with the remaining left two capacitance.
- Use series equivalent capacitance expression again finally to get the equivalent capacitance.
Chapter 22

Magnetic force

22.1 Magnetic field

The concepts introduced in electrostatics can be summarized in the following symbolic form:

\[ \text{Charge } q_1 \rightarrow \text{Electric field } (\vec{E}_1) \rightarrow \text{Charge } q_2 \text{ feels a force } \vec{F}_{21} = q_2 \vec{E}_1 \]

That is, a charge \( q_1 \) creates an electric field \( \vec{E}_1 \) which exerts a force \( \vec{F}_{21} \) on another charge \( q_2 \). A moving charge, in addition to the above, leads to a new phenomenon. A moving charge creates a magnetic field which exerts a force on another moving charge. This is summarized in the form:

\[ \text{Moving charge } q_1 \vec{v}_1 \rightarrow \text{Magnetic field } (\vec{B}_1) \rightarrow \text{Moving charge } q_2 \vec{v}_2 \text{ feels a force } \vec{F}_{21} = q_2 \vec{v}_2 \times \vec{B}_1 \]

Thus, a charge \( q \) moving with velocity \( \vec{v} \), represented by \( q\vec{v} \) (22.1)

or the corresponding current due to the movement of the charge, is a source of magnetic field. A manifestation of this phenomena at the microscopic level is seen in the interaction of two magnets, where the magnetic field due to one magnet exerts a force on the second magnet.

The Magnetic field is measured in units of Tesla=N·s/C·m. The common magnetic fields we come across is listed in Table 22.1.

22.2 Magnetic force

The force on a charge \( q \) moving with velocity \( \vec{v} \) in a magnetic field \( \vec{B} \) is symbolically given by

\[ \vec{F} = q\vec{v} \times \vec{B}. \] (22.2)

| \( 10^8 \) T  | magnetic field of a neutron star |
| \( 10^2 \) T  | strength of a laboratory magnet |
| \( 10^1 \) T  | medical MRI |
| \( 10^0 \) T  | a neodymium magnet |
| \( 10^{-3} \) T | a refrigerator magnet |
| \( 10^{-4} \) T | strength on surface of Earth |
| \( 10^{-12} \) T | human brain |

Table 22.1: Orders of magnitude (magnetic field)
The magnitude of the magnetic force $\vec{F}$ is given by

$$F = qvB \sin \theta,$$  \hspace{1cm} (22.3)

and the direction of the force is given by the right-hand rule. The right-hand rule is a mnemonic that associates the thumb to the velocity vector, the fingers to the magnetic field, and the force in the direction facing the palm of the right hand. The right-hand rule applies to a positive charge. For a negative charge the direction of force is flipped.

In discussions concerning the magnetic force we often have quantities pointing in and out of a plane. We shall use the notation $\bigcirc$ to represent a direction coming out of the plane, and $\bigotimes$ to represent a direction going into the plane. As a mnemonic one associates the dot with the tip of an arrow coming out of the page and the cross with the feathers of an arrow going into the page.

**Lecture-Example 22.1:**
A proton and an electron enters a region containing a magnetic field going into the page, $\vec{B} = -2.0 \hat{z}$ T. Let the velocity of both the particles while they enter the region be to the right, $\vec{v} = 3.0 \times 10^5 \hat{x}$ m/s.

- Determine the magnitude of the magnetic force on the proton and the electron.
- Determine the direction of the magnetic force on the proton and the electron, using the right-hand rule.
- Determine the corresponding accelerations experienced the proton and the electron.

**22.3 Motion of a charged particle in a uniform magnetic field**

In a uniform magnetic $\vec{B}$, if the velocity of a particle $\vec{v}$ is perpendicular to the direction of the magnetic field, the direction of the acceleration of the particle is always perpendicular to the velocity of the particle and to the magnetic field. Further, for the case of uniform magnetic field the magnitude of the acceleration remains constant. These are the requirements for a particle to move in a circle with uniform speed. Thus, using Newton’s law, $F = ma$, for circular motion, we have

$$qvB = m\frac{v^2}{R},$$  \hspace{1cm} (22.4)

where $R$ is the radius of the circle and $\omega$ is the angular frequency of the rotational motion, such that where $v = \omega R$. We learn that the particle particle goes around the magnetic field at an angular frequency, the cyclotron frequency, given by

$$\omega = \frac{q}{m} B,$$  \hspace{1cm} (22.5)

which depends on the charge to mass ratio of the particle.

For the more general case of the velocity not being perpendicular to the magnetic field the particle drifts in the direction of the magnetic field while moving in circles, the path covered being helical.

**Lecture-Example 22.2:** (Northern lights)
A proton and an electron are moving in circles around a magnetic field of $B = 1.0 \times 10^{-6}$ T.

- Determine the cyclotron frequency for the proton and the electron.
  (Answer: $\omega_p = 96$ rad/s, $\omega_e = 1.8 \times 10^5$ rad/s.)
- If the particles are moving with uniform speed $v = 2.0 \times 10^6$ m/s, determine the radius of the circles describing their path. (Answer: $R_p = 21$ km, $R_e = 11$ m.)
• Aurora Borealis (northern lights) and Aurora Australis (southern lights) is a spectacular display of light shimmering across the night sky, often observed around magnetic poles of the Earth, when charged particles emitted by the Sun and guided along by the magnetic field of the Earth enter the atmosphere. Check out an animation of this phenomenon as seen from space, released by NASA Earth Observatory, Aurora Australis on 2005 Sep 11, which to an observer on Earth would appear as a curtain of shimmering light.

**Lecture-Example 22.3:** (Bubble chamber)
Refer to the following tutorial at CERN: How to read Bubble Chamber pictures.

**Lecture-Example 22.4:** (Velocity selector)
The electric field and the magnetic field both deflect charged particles due to the respective forces. In a velocity selector these forces are exactly balanced for particles moving with a particular velocity which go through undeviated. Show that the velocity of a velocity selector is determined by

\[ v = \frac{E}{B}. \] (22.6)

- Determine the velocity selected by a velocity selector consisting of an electric field of \( E = 3.0 \times 10^5 \text{ N/C} \) and a magnetic field of \( B = 1.5 \text{ T} \). (Answer: \( v = 2.0 \times 10^5 \text{ m/s} \).)

**Lecture-Example 22.5:** (Applications)
- Mass spectrometer
- Hall effect
- Cyclotron
- Cathode ray tube

### 22.4 Magnetic force on a current carrying wire

Using the fact that a current carrying wire involves the motion of positive positive charges we realize that the wire will experience a magnetic force in a magnetic field. Identifying the relation

\[ qv = qL \frac{I}{t} = IL, \] (22.7)

where \( I \) is the current in the wire, we derive the force on a current carrying wire of length \( L \) to be

\[ F = ILB \sin \theta. \] (22.8)

The direction of the force is given using the right-hand rule with the thumb in the direction of current.

**Lecture-Example 22.6:**
A loop in the shape of a right triangle, carrying a current \( I \), is placed in a magnetic field. (Choose \( \hat{z} \) to be out of the page.)
• The force on side 1 is given by
  \[ \vec{F}_1 = IB_x \sin 180^\circ \hat{z} = 0 \hat{z}. \]  
  (22.9)

The force on side 2 is given by
  \[ \vec{F}_2 = -IB_y \sin 90^\circ \hat{z} = -IB_y \hat{z}. \]  
  (22.10)

The force on side 3 is given by, using \( \sin \theta = y/\sqrt{x^2 + y^2} \),
  \[ \vec{F}_3 = IB \sqrt{x^2 + y^2} \sin \theta \hat{z} = IB y \hat{z}. \]  
  (22.11)

• Show that the total force on the triangle is zero.

---

Lecture-Example 22.7:
A loop in the shape of a right triangle, carrying a current \( I \), is placed in a magnetic field. (Choose \( \hat{z} \) to be out of the page.)

• The force on side 1 is given by
  \[ \vec{F}_1 = -IB_x \sin 90^\circ \hat{y} = -IB_x \hat{y}. \]  
  (22.12)

The force on side 2 is given by
  \[ \vec{F}_2 = -IB_y \sin 90^\circ \hat{x} = -IB_y \hat{x}. \]  
  (22.13)

The force on side 3 is given by, using \( \sin \theta = y/\sqrt{x^2 + y^2} \),
  \[ \vec{F}_3 = IB \sqrt{x^2 + y^2} \sin \theta \hat{x} + IB \sqrt{x^2 + y^2} \cos \theta \hat{y} = IB y \hat{x} + IB x \hat{y}. \]  
  (22.14)

• Show that the total force on the triangle is zero.
22.5 Magnetic moment of a current carrying loop

The magnetic moment $\vec{\mu}$ associated with a (planar) current carrying loop of wire is

$$\vec{\mu} = NIA\hat{n}, \quad (22.15)$$

where $I$ is the current in the wire, $N$ is the number of turns in the loop, and $A$ is the area of the loop. The direction of the magnetic moment, represented by $\hat{n}$, is perpendicular to the plane constituting the loop and is given by the right-hand rule. An arbitrary shaped loop that is not planar can be constructed out of infinitely small planar loops.

A magnet is interpreted to have a North and South pole, in the Gilbert model. In the Ampère model the magnetic field due to a magnet is due to microscopic current loops. The magnetic moment of a magnet characterizes the strength of a magnetic field produced by the magnet.

**Force**

The total force on a current carrying loop in a uniform magnetic field is zero.

**Torque**

The magnitude of the torque on a current carrying loop, or just a magnetic moment $\vec{\mu}$, in a uniform magnetic field $\vec{B}$, is

$$\tau = \mu B \sin \theta, \quad (22.16)$$

where $\theta$ is the angle between the direction of the magnetic moment $\vec{\mu}$ and the magnetic field $\vec{B}$. The direction is such that the magnetic moment tries to align with the magnetic field.

**Lecture-Example 22.8:**

A loop in the shape of a rectangle, carrying a current $I$, is placed in a magnetic field. Let the plane of the loop be perpendicular to the magnetic field $\vec{B} = -B\hat{z}$.

![Figure 22.3: Lecture-Example 22.8](image)

- The force on side 1 is given by

  $$\vec{F}_1 = -\hat{y} IL_x B \sin 90^\circ = -\hat{y} IL_x B. \quad (22.17)$$

  The force on side 2 is given by

  $$\vec{F}_2 = -\hat{x} IL_y B \sin 90^\circ = -\hat{x} IL_y B. \quad (22.18)$$

  The force on side 3 is given by

  $$\vec{F}_3 = +\hat{y} IL_x B \sin 90^\circ = +\hat{y} IL_x B. \quad (22.19)$$
The force on side 4 is given by
\[ \vec{F}_4 = +\hat{x} IL_y B \sin 90^\circ = +\hat{x} IL_y B. \] (22.20)

- Show that the total force on the rectangle is zero.
- Show that the total torque on the rectangle is zero.

**Lecture-Example 22.9:**
A loop in the shape of a rectangle, carrying a current \( I \), is placed in a magnetic field. Let the normal to the plane of the loop make an angle \( \theta \) with respect to the magnetic field \( \vec{B} = -B \hat{z} \).

![Diagram of loop in magnetic field](image)

- The force on side 1 is given by
  \[ \vec{F}_1 = -\hat{y} IL_x B \sin 90^\circ = -\hat{y} IL_x B. \] (22.21)

The force on side 2 is given by
\[ \vec{F}_2 = -\hat{x} IL_y B \sin(90^\circ + \theta) = -\hat{x} IL_y B \cos \theta. \] (22.22)

The force on side 3 is given by
\[ \vec{F}_3 = +\hat{y} IL_x B \sin 90^\circ = +\hat{y} IL_x B. \] (22.23)

The force on side 4 is given by
\[ \vec{F}_4 = +\hat{x} IL_y B \sin(90^\circ - \theta) = +\hat{x} IL_y B \cos \theta. \] (22.24)

- Show that the total force on the rectangle is zero.
- Show that the total torque on the rectangle is
\[ \tau = \frac{L_y}{2} F_3 \sin \theta + \frac{L_y}{2} F_1 \sin \theta = \mu B \sin \theta. \] (22.25)
22.6 Homework problems

**Homework-Problem 22.1:**

(a) A proton, traveling with a velocity of $3.9 \times 10^6$ m/s due east, experiences a magnetic force that has a maximum magnitude of $8.4 \times 10^{-14}$ N and a direction of due south. What are the magnitude and direction of the magnetic field causing the force?

(b) Repeat part (a) assuming the proton is replaced by an electron.

**Hints:**

- Use Right-Hand Rule No. 1 (RHR-1) to find the direction of the magnetic field.
- Determine angle $\theta$ between the velocity direction and the magnetic field direction.
- Use

$$F_m = |q|vB\sin\theta, \quad \ldots \quad (22.26)$$

to solve for the magnitude of the magnetic field. Here, $F_m$ is the magnetic force, $|q|$ is the magnitude of the charge of the particle, $v$ is the velocity of the charged particle, and $B$ is the magnetic field experienced by the particle.

- Use RHR-1 again for the negatively charged electron to determine direction of the magnetic field.
- Does magnitude of the magnetic field for the electron change?

**Homework-Problem 22.2:** A charge of $-8 \mu C$ is traveling at a speed of $7.7 \times 10^6$ m/s in a region of space where there is a magnetic field. The angle between the velocity of the charge and the field is 58°. A force of magnitude $5.1 \times 10^{-3}$ N acts on the charge. What is the magnitude of the magnetic field?

**Hints:**

Use Eq. (22.26) to solve for the magnitude of the magnetic field.

**Homework-Problem 22.3:** A magnetic field has a magnitude of $1.20 \times 10^{-3}$ T, and an electric field has a magnitude of $5.30 \times 10^3$ N/C. Both fields point in the same direction. A positive $1.8 \mu C$ charge moves at a speed of $3.40 \times 10^6$ m/s in a direction that is perpendicular to both fields. Determine the magnitude of the net force that acts on the charge.

**Hints:**

- Use

$$\vec{F}_e = q\vec{E}, \quad \ldots \quad (22.27)$$

to find the magnitude of the electric force on the charge. Note that this force is in the direction of the electric field.

- Use Eq. (22.26) to find the magnitude of the magnetic force on the charge. Note that direction of this force will be perpendicular to the direction of the magnetic field.
- Use $F_{\text{net}} = \sqrt{F_e^2 + F_m^2}$ to find net force on the charge.
  ($F_e$ and $F_m$ are perpendicular to each other.)

**Homework-Problem 22.4:** A charged particle with a charge-to-mass ratio of $|q|/m = 5.7 \times 10^8 \text{C/kg}$ travels on a circular path that is perpendicular to a magnetic field whose magnitude is 0.66 T. How much time does it take for the particle to complete one revolution?

**Hints:**
- The magnetic force for a charged particle moving on a circular path that is perpendicular to a magnetic field is $F_m = qvB$.
- This force is providing the necessary centripetal force for the particle’s motion,
  \[qvB = \frac{mv^2}{R},\]  \[(22.28)\]
  where $R$ is the radius of the circular path.
- If particle takes time $T$ for one revolution then its average velocity is given by
  \[v = \frac{2\pi R}{T},\]  \[(22.29)\]
- Use Eqs. (22.28) and (22.29) for find an expression for time $T$. Solve for $T$.

**Homework-Problem 22.5:** A charge particle enters a uniform magnetic field and follows the circular path shown in the drawing.

(a) Is the particle positively or negatively charged?

(b) The particle's speed is 140 m/s, the magnitude of the magnetic field is 0.48 T, and the radius of the path is 960 m. Determine the mass of the particle, given that its charge has a magnitude of $8.2 \times 10^{-4}$ C.

**Hints:**

Figure 22.5: Homework-Problem 22.5.
• Velocity of a particle on a circular path is tangential at each point.
• Use RHR-1 to determine the direction of the magnetic force for a positive charge. Is the particle in the figure turning in the direction of this force or opposite?
• Use Eq. (22.28) to solve for mass.

**Homework-Problem 22.6:** When beryllium-7 ions \((m = 1.165 \times 10^{-26} \text{ kg})\) pass through a mass spectrometer, a uniform magnetic field of 0.2280 T curves their path directly to the center of the detector (see figure below). For the same accelerating potential difference, what magnetic field should be used to send beryllium-10 ions \((m = 1.663 \times 10^{-26} \text{ kg})\) to the same location in the detector? Both types of ions are singly ionized \((q = +e)\)

![Figure 22.6: Homework-Problem 22.6.](image)

**Hints:**

• The potential energy \(qV\) is converted into kinetic energy \(\frac{1}{2}mv^2\). Thus, the velocity of the ion on entering the mass spectrometer is

\[
v = \sqrt{\frac{2qV}{m}}.
\]  
(22.30)

• Use Eqs. (22.28) and (22.30) to obtain

\[
B = \frac{1}{R} \sqrt{\frac{2mV}{q}}.
\]  
(22.31)

• Note that charge\((q)\), radius\((R)\), and accelerating potential\((V)\) are same for both cases so taking ratio of the expression of the magnetic field when beryllium-7 ions were passing through the detector \((B_1)\) and the expression of the magnetic field when beryllium-10 ions were passing \((B_2)\) find that

\[
\frac{B_1}{B_2} = \sqrt{\frac{m_1}{m_2}},
\]  
(22.32)

where \(m_1\) is the mass of the beryllium-7 ion and \(m_2\) is the mass of the beryllium-7 ion.

• Find \(B_2\) using given information.
CHAPTER 22. MAGNETIC FORCE

Homework-Problem 22.7: Suppose that an ion source in a mass spectrometer produces doubly ionized gold ions (Au$^{2+}$), each with a mass of $3.27 \times 10^{-25}$ kg. The ions are accelerated from rest through a potential difference of $1.21$ kV. Then, a $0.445$ T magnetic field causes the ions to follow a circular path. Determine the radius of the path.

Hints:
Use Eq. (22.31) to solve for radius $R$ with the given information. Note that the charge $q = +2e$ for Au$^{2+}$ ion.

Homework-Problem 22.8: A proton with a speed of $3.52 \times 10^6$ m/s is shot into a region between two plates that are separated by a distance of $0.18$ m. As the drawing shows, a magnetic field exists between the plates, and it is perpendicular to the velocity of the proton. What must be the magnitude of the magnetic field so the proton just misses colliding with the opposite plate?

Hints:
- The proton moves on a circular path between the plates because the magnetic field is acting perpendicular to the velocity of the proton.
- If the proton just misses colliding with the opposite plate then the radius of the circular path it follows between the plates is equal to the distance between the plates.
- Use Eq. (22.28) to solve for the magnitude of the magnetic field ($B$).
- See interactive solutions on webassign for more details.

Homework-Problem 22.9: Review Conceptual Example 2 as an aid in understanding this problem. A velocity selector has an electric field of magnitude $2679$ N/C, directed vertically upward, and a horizontal magnetic field that is directed south. Charged particles, traveling east at a speed of $7.05 \times 10^3$ m/s, enter the velocity selector and are able to pass completely through without being deflected. When a different particle with an electric charge of $+3.84 \times 10^{-12}$ C enters the velocity selector traveling east, the net force (due to the electric and magnetic fields) acting on it is $1.95 \times 10^{-9}$ N, pointing directly upward. What is the speed of this particle?

Hints:
- The electric field is acting out of the paper, velocity of the particle towards east in the plane of the paper, and the magnetic field is acting down south in the plane of paper.
• For an undeflected particle \( v = \frac{E}{B} \). Use it to find the magnitude of the magnetic field \( B \).

• For the different particle use net force, \(|F_{\text{net}}| = |F_e - F_m|\), acting on the particle and \( F_e = qE \) to find value of the magnetic force \( F_m \).

• Use Eq. (22.26) to solve for \( v \).

**Homework-Problem 22.10:** A straight wire in a magnetic field experiences a force of 0.028 N when the current in the wire is 2.6 A. The current in the wire is changed, and the wire experiences a force of 0.045 N as a result. What is the new current?

**Hints:**
Use
\[ F = ILB \sin \theta, \]  
(22.33)
to write the ratio of forces in two cases. *Note that only current is changing.*

**Homework-Problem 22.11:** A wire carries a current of 0.66 A. This wire makes an angle of 58° with respect to a magnetic field of magnitude \( 6.00 \times 10^{-5} \) T. The wire experiences a magnetic force of magnitude \( 8.30 \times 10^{-5} \) N. What is the length of the wire?

**Hints:**
Use information given in the problem in Eq. (22.33) to solve for length of the wire \( L \).

**Homework-Problem 22.12:** A loop of wire has the shape of a right triangle (see the drawing) and carries a current of \( I = 4.30 \) A. A uniform magnetic field is directed parallel to side AB and has a magnitude of 1.70 T.

![Figure 22.8: Homework-Problem 22.12.](image)

(a) Find the magnitude and direction of the magnetic force exerted on each side of the triangle.

(b) Determine the magnitude of the net force exerted on the triangle.

**Hints:**
• Use Eq. (22.33) to find magnitude of the magnetic force. You will need to determine length of the each side and the angle \( \theta \) it makes with magnetic field \( B \).

• Determine the directions for the magnetic force acting on each side using RHR-1.

• Net force is the sum of all the forces. Keeping into account their respective directions.
Chapter 23

Magnetic field due to currents

23.1 Magnetic field due to currents

A straight segment of wire

The magnetic field due to a straight segment of wire at a distance \( r \) from the wire is

\[
B = \frac{\mu_0 I}{4\pi r} (\sin \theta_1 + \sin \theta_2),
\]

(23.1)

where the angles \( \theta_1 \) and \( \theta_2 \) specifies the observation point with respect to the ends of the wire. See Figure 23.1. The direction of the magnetic field is given by the right-hand rule. As a special case, we have the magnetic field due to an infinitely long wire, \( \theta_1 = \theta_2 = \pi/2 \), as

\[
B = \frac{\mu_0 I}{2\pi r}.
\]

(23.2)

The constant \( \mu_0 \) is the permeability of vacuum,

\[
\mu_0 = 4\pi \times 10^{-7} \text{T} \cdot \text{m} / \text{A}.
\]

(23.3)

A circular segment of wire

The magnetic field due a circular segment of wire, at the center of circle, is

\[
B = \frac{\mu_0 I}{4\pi R} \theta,
\]

(23.4)

where the angle \( \theta \) is the angular measure of the segment. See Figure 23.2. The direction of the magnetic field is given by the right-hand rule. As a special case, we have the magnetic field due to a circular loop of wire,
CHAPTER 23. MAGNETIC FIELD DUE TO CURRENTS

\[ B = \frac{\mu_0 I}{2R} \]

(23.5)

\[ B = \begin{cases} \mu_0 I n, & \text{inside,} \\ 0, & \text{outside,} \end{cases} \]

(23.6)

where \( n = N/L \) is the number of turns \( N \) per unit length \( L \).

**Lecture-Example 23.1:** A steady current \( I \) flows through a wire shown in Fig. 23.3. Show that the magnitude and direction of magnetic field at point \( P \) is

\[ B = \frac{\mu_0 I}{4\pi a} \left( \frac{2}{2} + \frac{2}{2} + \frac{2\pi}{2} \right) \]

(23.7)

coming out of the page.

- Determine the magnitude and direction of the magnetic field for \( I = 1.0 \, \text{A} \) and \( a = 10.0 \, \text{cm} \).
- Determine the magnitude and direction of the magnetic force on a proton moving with velocity \( v = 2.0 \times 10^6 \, \text{m/s} \), to the right, while it is passing the point \( P \).

**Lecture-Example 23.2:** A steady current \( I \) flows through a wire shown in Fig. 23.4. Show that the magnitude and direction of magnetic field at point \( P \) is

\[ B = \frac{\mu_0 I}{4\pi a} \left( \frac{2}{2} + \frac{2}{2} + \frac{2\pi}{4} \right) \]

(23.8)
23.1. Magnetic Field Due to Currents

• Determine the magnitude and direction of the magnetic field for \( I = 1.0 \text{ A} \) and \( a = 10.0 \text{ cm} \).

• Determine the magnitude and direction of the magnetic force on a proton moving with velocity \( \mathbf{v} = 2.0 \times 10^6 \text{ m/s} \), to the right, while it is passing the point \( P \).

Lecture-Example 23.3: A steady current \( I \) flows through a wire in the shape of a square of side \( L \), shown in Fig. 23.5. Show that the magnitude and direction of the magnetic field at the center of the square, \( P \), is

\[
B = \frac{\mu_0 I}{\pi L} \frac{A}{\sqrt{2}} \quad (23.9)
\]

going out of the page.

Lecture-Example 23.4: Figure 23.6 shows two current carrying wires, separated by a distance \( D \). The directions of currents, either going into the page or coming out of the page, are shown in the figure. Determine the point \( x \) where the magnetic field is exactly zero.

• Answer:

\[
x = \frac{D}{\left(1 + \frac{I_1}{I_2}\right)} \quad (23.10)
\]

Determine \( x \) if \( I_1 = 2.0 \text{ A} \), \( I_2 = 6.0 \text{ A} \), and \( D = 10.0 \text{ cm} \). (Answer: 2.5 A.)

• How does your answer change if the direction of currents in either or both the wires were changed?
CHAPTER 23. MAGNETIC FIELD DUE TO CURRENTS

Figure 23.6: Lecture-Example 23.4

Lecture-Example 23.5:
Figure 23.7 shows two current carrying wires, in a plane. The directions of currents, either going into the page or coming out of the page, are shown in the figure. Determine the magnitude and direction of the magnetic field at the point $x$, the origin. Let $I_1 = 1.0 \, \text{A}$, $I_2 = 2.0 \, \text{A}$, $x = 12 \, \text{cm}$, and $y = 8.0 \, \text{cm}$.

- The magnetic field at the origin due to the individual wires is

  $$\vec{B}_1 = \frac{\mu_0 I_1}{2\pi y} \hat{i} + 0 \hat{j}, \quad (23.11a)$$

  $$\vec{B}_2 = 0 \hat{i} + \frac{\mu_0 I_2}{2\pi x} \hat{j}. \quad (23.11b)$$

  The total magnetic field is given as

  $$\vec{B}_{\text{tot}} = \vec{B}_1 + \vec{B}_2. \quad (23.12)$$

  Answer: $\vec{B}_1 = \hat{i} 2.5 \, \mu\text{T}$ and $\vec{B}_2 = \hat{j} 3.3 \, \mu\text{T}$. Magnitude $|\vec{B}_{\text{tot}}| = 4.1 \, \mu\text{T}$ makes an angle of $53^\circ$ counterclockwise with respect to $x$-axis.

- How does your answer change if the direction of currents in either or both the wires were changed?

Lecture-Example 23.6:
A 200 turn solenoid having a length of $20.0 \, \text{cm}$ and a diameter of $1.0 \, \text{cm}$ carries a current of $1.0 \, \text{A}$. Calculate the magnitude of the magnetic field $B$ inside the solenoid.

- Since the diameter is sufficiently less than the length of the solenoid we can approximate the solenoid to be of infinite length. (Answer: $B = 1.3 \, \text{mT}$.)
23.2 Force between parallel current carrying wires

If we have two parallel current carrying wires, each of the wires generates a magnetic field around it, which in turn exerts a force on the other wire. For currents $I_1$ and $I_2$ in the wires separated by a distance $r$ we have the force per unit length on the wires given by

$$\frac{F}{L} = \frac{\mu_0 I_1 I_2}{2\pi r}.$$  \hspace{1cm} (23.13)

The direction of the force is such that the wires attract if the currents are in the same direction, and vice versa. We say, like currents attract and unlike current repel.

**Lecture-Example 23.7:**

Two infinitely long parallel wires, carrying currents $I_1 = 1.0 \text{ A}$ and $I_2 = 2.0 \text{ A}$ in the same direction, are separated by a distance $r = 10 \text{ cm}$.

- Determine the magnitude and direction of the magnetic field $\vec{B}_1$ generated by the current $I_1$ at the position of current $I_2$. (Answer: $B_1 = 2.0 \mu \text{T}$.) Determine the magnitude and direction of the force exerted by the magnetic field $\vec{B}_1$ on the wire with current $I_2$. (Answer: $4.0 \mu \text{N}$.)

- How will the answer differ if the currents are in opposite directions?

**Lecture-Example 23.8:**

A rectangular loop of wire carrying current $I_2 = 2.0 \text{ A}$ is placed near an infinitely long wire carrying current $I_1 = 1.0 \text{ A}$, such that two of the sides of the rectangle are parallel to the current $I_1$. Let the distances be $a = 5.0 \text{ cm}$, $b = 4.0 \text{ cm}$, and $l = 10.0 \text{ cm}$.

![Figure 23.8: Lecture-Example 23.8](image)

- Determine the force on side ‘1’ of the loop. (Answer: $0.44 \mu \text{N}$ away from the current carrying wire $I_1$.)

- Determine the force on side ‘3’ of the loop. (Answer: $0.80 \mu \text{N}$ towards the current carrying wire $I_1$.)

Further, show that the combined force on side ‘2’ and ‘3’ is zero. Determine the magnitude and direction of the total force on the loop. (Answer: $0.36 \mu \text{N}$ towards the current carrying wire $I_1$.)

- How does your analysis change if either of the currents were reversed?

23.3 Ampère’s law

Ampère’s law states that the total sum of the magnetic field $\vec{B}$ along a closed path is completely determined by the total current $I_{en}$ passing through the closed path,

$$\sum B \Delta l \cos \theta = \mu_0 I_{en}.$$  \hspace{1cm} (23.14)
Lecture-Example 23.9: (Magnetic field due to an infinitely long current carrying wire)

Using the symmetry of an infinitely long straight wire, presuming the magnetic field to be circular, derive the magnetic field around the wire using Ampère’s law,

$$\vec{B} = \hat{\varphi} \frac{\mu_0 I}{2\pi r}.$$  (23.15)

Lecture-Example 23.10: (Solenoid)

Using Ampère’s law show that the magnetic field due to a solenoid is given by,

$$\vec{B} = \begin{cases} \hat{z} \mu_0 n, & \text{inside}, \\ 0, & \text{outside}. \end{cases}$$  (23.16)

23.4 Homework problems

Homework-Problem 23.1: A wire has a length of $7.20 \times 10^{-2}$ m and is used to make a circular coil of one turn. There is a current of 2.70 A in the wire. In the presence of a 1.10 T magnetic field, what is the maximum torque that this coil can experience?

Hints:

- Find area ($A$) of the circular coil using information given about the length (circumference) of the wire.
- Use equation

$$\tau = \mu B \sin \phi = NIAB \sin \phi,$$  (23.17)

to find the torque. Maximum torque happens when the area vector (normal to the plane of the loop) is perpendicular to the direction of the magnetic field, $\phi = \frac{\pi}{2}$.

Homework-Problem 23.2: The rectangular loop in the drawing consists of 65 turns and carries a current of $I = 4.0$ A. A 1.0 T magnetic field is directed along the $+y$ axis. The loop is free to rotate about the $z$ axis. ($\theta = 33^\circ$)

(a) Determine the magnitude of the net torque exerted on the loop.

(b) State whether the 33° angle will increase or decrease.

Hints:

- Plane of the loop makes angle $\theta$ with the magnetic field $B$. Thus the area vector (normal to the plane of the loop) will make angle $\phi = 90 - \theta$ with the magnetic field.
- Use Eq. (23.17) to find the magnitude of the torque.
• Torque on the loop tries to reduce angle $\phi$ between the area vector and the magnetic field. What will happen to angle $\theta$ if angle $\phi$ decreases?

**Homework-Problem 23.3:** A long solenoid has a length of 0.72 m and contains 1265 turns of wire. There is a current of 5.4 A in the wire. What is the magnitude of the magnetic field within the solenoid?

**Hints:** Use expression for the magnetic field inside a long solenoid:

$$B = \mu_0 n I = \mu_0 \left( \frac{N}{L} \right) I. \quad (23.18)$$

Here, $n$ is the number of turns per unit length and $N$ is the number of turns.

**Homework-Problem 23.4:** The magnetic field produced by the solenoid in a magnetic resonance imaging (MRI) system designed for measurements on whole human bodies has a field strength of 10.0 T, and the current in the solenoid is $3.0 \times 10^2$ A. What is the number of turns per meter of length of the solenoid? Note that the solenoid used to produce the magnetic field in this type of system has a length that is not very long compared to its diameter. Because of this and other design considerations, your answer will be only an approximation.

**Hints:** Use Eq. (23.18) to find number of turns per unit length ($n$).

**Homework-Problem 23.5:** Two long, straight wires are separated by 0.12 m. The wires carry currents of 3.5 A in opposite directions, as the drawing indicates.

(a) Find the magnitude of the net magnetic field at the point A.

(b) Find the magnitude of the net magnetic field at the point B.

**Hints:**
• The magnitude of the magnetic field \( B \) due to a long wire carrying current \( I \) at a distance \( r \) is

\[
B = \frac{\mu_0 I}{2\pi r}.
\]  

\( (23.19) \)

• Use above equation to find magnitude of the magnetic field at point in question due to each wire separately \((B_1 \text{ and } B_2)\).

• Determine the direction of \( B_1 \) and \( B_2 \) using Right hand rule No. 2 (RHR-2) at that point.

• Find the magnitude of the net (total) magnetic field at asked point, taking care of the directions of \( B_1 \) and \( B_2 \). In vector notation this is expressed as

\[
\vec{B}_{net} = \vec{B}_1 + \vec{B}_2
\]

\( (23.20) \)

**Homework-Problem 23.6:** A long, straight wire carrying a current of 390 A is placed in a uniform magnetic field that has a magnitude of \( 6.50 \times 10^{-3} \text{T} \). The wire is perpendicular to the field. Find a point in space where the net magnetic field is zero. Locate this point by specifying its perpendicular distance from the wire.

**Hints:**

• Draw figure for the problem with uniform magnetic field \((\vec{B}_1)\) coming out of the paper and the current carrying wire in the plane of the paper. The magnetic field \((\vec{B}_2)\) due to the wire is going into the paper.

\[
\vec{B}_1 - \vec{B}_2 = 0 \quad \Rightarrow \quad B_1 - B_2 = 0
\]

\( (23.21) \)
• Use Eq. (23.19) to write expression for \( B_2 \). Solve for distance \( r \) using above equation.

**Homework-Problem 23.7:** Two circular coils are concentric and lie in the same plane. The inner coil contains 120 turns of wire, has a radius of 0.012 m and carries a current of 5.5 A. The outer coil contains 165 turns and has a radius of 0.017 m. What must be the magnitude and direction (relative to the current in the inner coil) of the current in the outer coil, such that the net magnetic field at the common center of the two coils is zero?

**Hints:**

• Use

\[
B = N \frac{\mu_0 I}{2R}
\]

(23.22)

to determine the magnitude of the magnetic field at the center due to the inner coil. Here, \( N \) is the number of turns.

• To get zero net magnetic field at the center, the magnetic field due to the outer coil should be equal in magnitude and opposite in direction to the magnetic field due to the inner coil. Use this fact to determine magnitude of the current in the outer coil using Eq. (23.22).

• See interactive solution on webassign for more details.

**Homework-Problem 23.8:** Two infinitely long, straight wires are parallel and separated by a distance of \( D = 1.49 \) meters. They carry currents in the same direction. Wire 1 carries two times the current that wire 2 carries. On a line drawn perpendicular to both wires, locate the spot (relative to wire 1) where the net magnetic field is zero. Assume that wire 1 lies to the left of wire 2 and note that there are three regions to consider on this line: to the left of wire 1, between wire 1 and wire 2, and to the right of wire 2.

**Hints:**

• Draw figure and find direction of the magnetic fields due to two wires in three regions. Convince yourself that two magnetic fields could add up to zero only in the middle region as shown below (where they are in opposite directions).

![Figure 23.12: Homework-Problem 23.8](image)

• Write expression for the magnitude of \( \vec{B}_1 \) and \( \vec{B}_2 \) using Eq. (23.19) at a point \( r = x \) distance away. **Note that the distance of this point from the second wire is** \( r = D - x \).

• For net magnetic field to be zero:

\[
\vec{B}_1 + \vec{B}_2 = 0 \quad \Rightarrow \quad B_1 - B_2 = 0
\]

(23.23)

Use above equation to solve for \( x \).
**Homework-Problem 23.9:** The wire in the figure below carries a current of 11 A. Suppose that a second long, straight wire is placed right next to this wire. The current in the second wire is 24 A. Use Ampere's law to find the magnitude of the magnetic field at a distance of \( r = 0.72 \text{ m} \) from the wires when the currents are in the same direction and in opposite directions.

![Homework-Problem 23.9](image)

**Hints:** Use Ampère’s law for a circular loop,

\[
\sum B \Delta l = \mu_0 I_{\text{encl}}. \tag{23.24}
\]

Here \( \Delta l = 2\pi r \) for a circular loop and \( I_{\text{encl}} \) is the total current enclosed inside the Ampèrian loop. *Take the direction of flow of currents into account when finding \( I_{\text{encl}} \).*

**Homework-Problem 23.10:** A very long, hollow cylinder is formed by rolling up a thin sheet of copper. Electric charges flow along the copper sheet parallel to the axis of the cylinder. The arrangement is, in effect, a hollow tube of current \( I \). Use Ampère’s law to show that the magnetic field (a) is \( \mu_0 I(2\pi r) \) outside the cylinder at a distance \( r \) from the axis and (b) is zero at any point within the hollow interior of the cylinder. (Hint: For closed paths, use circles perpendicular to and centered on the axis of the cylinder. Do this on paper. Your instructor may ask you to turn in this work.)

**Hints:**
- Draw a circular Ampèrian loop of radius \( r \) outside the current carrying cylinder at distance \( r \). *What is the total current enclosed in the loop, \( I_{\text{encl}} \), in this case?*
- Draw another circular Ampèrian loop inside the hollow cylinder. *What is the total current enclosed in the loop, \( I_{\text{encl}} \), in this case?*
- Use Eq. (23.24) to find magnetic field in both cases.
Chapter 24

Faraday Induction

24.1 Magnetic flux

Flux associated with the magnetic field $\vec{B}$ across an infinitesimal area $\mathbf{A}$ is defined as

$$\Phi_B = BA \cos \theta,$$

(24.1)

where $\theta$ is the angle between the vectors. Gauss’s law for magnetism states that the magnetic flux across a closed surface is zero, that is

$$\Phi_B \bigg|_{\text{closed surface}} = 0,$$

(24.2)

which implies the absence of an isolated magnetic monopole, or the magnetic charge. In other words it states that the north pole and the south pole of a bar magnet can not be separated.

Lecture-Example 24.1: A square loop of wire consisting of a single turn is perpendicular to a uniform magnetic field. The square loop is then re-formed into a circular loop and is also perpendicular to the same magnetic field. Determine the ratio of the flux through the square loop to the flux through the circular loop. (Answer: $\pi/4$.)

24.2 Faraday’s law of induction

Faraday’s law of induction states that the negative rate of change of magnetic flux passing a loop of wire induces an effective voltage in the loop, which in turn generates a current in the loop,

$$IR = \Delta V_{\text{eff}} = -N \frac{\Delta \Phi_B}{\Delta t},$$

(24.3)

where $N$ is the number of loops.

Lecture-Example 24.2: Consider a straight wire of length $L = 1.0\,\text{m}$ moving with velocity $v = 30.0\,\text{m/s}$ in the region of a uniform magnetic field $B = 2.0 \times 10^{-5}\,\text{T}$. Determine the potential difference induced between the ends of the wire. (Answer: 0.60 mV.)

Lecture-Example 24.3: (Induction due to change in area)
Figure 24.1 shows a conducting rod being pulled along horizontal, frictionless, conducting rails at a constant speed $v$. A uniform magnetic field $B$ fills the region in which the rod moves. Let $l = 10 \text{ cm}$, $v = 5.0 \text{ m/s}$, $B = 1.2 \text{ T}$, and $R = 0.40 \Omega$.

- Is the magnetic flux in the loop increasing or decreasing? What is the direction of the induced current in the loop?

- Show that the magnitude of the induced current in the loop is given by
  \[ I = \frac{Blv}{R}. \]  
  \[(24.4)\]

Show that this induced current feels a magnetic force of
\[ F_B = \frac{B^2l^2v}{R}. \]  
\[(24.5)\]

Determine the power delivered to the resistance due to the induced current is
\[ P = \frac{B^2l^2v^2}{R}. \]  
\[(24.6)\]

- How does the analysis change if the direction of velocity is reversed?

---

**Lecture-Example 24.4:**

Figure 24.2 shows five snapshots of a rectangular coil being pushed across the dotted region where there is a uniform magnetic field directed into the page. Outside of this region the magnetic field is zero.

- Determine the direction of induced current in the loop at each of the five instances in the figure.

- Determine the direction force on the loop due to the induced current in each of the five instances in the figure.

---

**Lecture-Example 24.5:** (Induction due to change in magnetic field)

A loop of wire having a resistance $R = 100.0 \Omega$ is placed in a magnetic field whose magnitude is changing in time, as described in Figure 24.3. The direction of the magnetic field is normal to the plane of the loop. The loop of wire consists of 50 turns and has an area of $A = 25 \times 10^{-4} \text{ m}^2$. 
24.2. FARADAY’S LAW OF INDUCTION

Figure 24.2: Lecture-Example 24.4

Figure 24.3: Lecture-Example 24.5

- Determine the induced voltage and the induced current in the loop between 0 s to 2 s. (Answer: $V = 0.13 \text{ V}$ and $I = 1.3 \text{ mA}$.) Determine the induced voltage and the induced current in the loop between 2 s to 4 s. (Answer: $V = 0$ and $I = 0$.) Determine the induced voltage and the induced current in the loop between 4 s to 5 s. (Answer: $V = 0.25 \text{ V}$ and $I = 2.5 \text{ A}$.)

Lecture-Example 24.6: (A simple transformer)
Consider two coils wound on the same cylinder such that the flux through both the coils is the same, such that

$$\frac{\Delta \Phi_1}{\Delta t} = \frac{\Delta \Phi_2}{\Delta t}. \quad (24.7)$$

Thus, derive the ratio of the voltages in the two coils to be given by

$$\frac{V_1}{V_2} = \frac{N_1}{N_2}. \quad (24.8)$$

Energy conservation requires the power in the coils to be the same, that is $P_1 = P_2$. Thus, further derive

$$\frac{I_2}{I_1} = \frac{N_1}{N_2}. \quad (24.9)$$

A device operates at $V_2 = 10.0 \text{ V}$. It uses a transformer to get the required voltage when plugged into a wall socket with voltage $V_1 = 120 \text{ V}$. Determine the ratio of the turns in the two coils inside the transformer. (Answer: $N_1/N_2 = 12$.) If the device pulls a current of 120 mA, determine the current coming out of the wall socket. (Answer: $I_1 = 10 \text{ mA}$.)
Lecture-Example 24.7: (Induction due to change in orientation)
Consider the area enclosed by the loop formed in the configuration shown in Figure 24.4. The rotation described in the figure effectively changes the area enclosed by the loop periodically.

\[ \Delta \cos \theta \Delta t = -\omega \sin \omega t, \]  
\[ \Delta V_{\text{eff}} = BA\omega \sin \omega t. \]  

Determine the maximum induced voltage for \( B = 0.1 \) T, radius \( a = 10\) cm, and angular speed of rotation of 600 revolutions per minute (\( \omega = 20\pi \) rad/s). (Answer: 0.20 V.)

- Plot the induced voltage as a function of time.

Lecture-Example 24.8: (Generator)
A generator has a square coil consisting of 500 turns. The coil rotates at 60 rad/s in a 0.20 T magnetic field. If length of one side of the coil is 10.0 cm, what is peak output of the generator? (Answer: 60 V.)

24.3 Homework problems

Homework-Problem 24.1: A 0.76 m aluminum bar is held with its length parallel to the east-west direction and dropped from a bridge. Just before the bar hits the river below, its speed is 24 m/s, and the emf induced across its length is \( 6.20 \times 10^4 \) V. Assume the horizontal component of the earth’s magnetic field at the location of the bar points directly north.

\( (a) \) Determine the magnitude of the horizontal component of the earth’s magnetic field.

\( (b) \) State whether the east end or the west end of the bar is positive.

Hints:
• Use

\[ E = vBL, \quad (24.12) \]

to determine the magnitude of the magnetic field \( B \). \( E \) is the induced emf, \( v \) is the velocity of the bar, and \( L \) is the length of the bar.

• Use Right Hand Rule-1 for negatively charged electrons to determine the direction of force on them. Positive charges will collect in the opposite direction.

*Keep in mind that electrons are negatively charged, so direction of the force predicted by RHR-1 reverses.*

**Homework-Problem 24.2:** Two circuits contain an emf produced by a moving metal rod, like that shown in the drawing. The speed of the rod is the same in each circuit, but the bulb in circuit 1 has one-half the resistance of the bulb in circuit 2. The circuits are otherwise identical. The resistance of the light bulb in circuit 1 is 300 \( \Omega \), and that in circuit 2 is 600 \( \Omega \).

![Image of two circuits](image.png)

Figure 24.5: Homework-Problem 24.2.

(a) Determine the ratio \( E_1/E_2 \) of the emfs.

(b) Determine the ratio \( I_1/I_2 \) of the currents in the circuits.

(c) If the speed of the rod in circuit 1 were twice that in circuit 2, what would be the ratio \( P_1/P_2 \) of the powers in the circuits?

**Hints:**

• Use Eq. \((24.12)\) to write expressions for emfs in circuits 1 and 2. Find the ratio. *Note that two rods have same speed and circuits are identical except for the resistances of the bulb in two cases.*

• Use Ohm’s law to write expression for the current in the circuit due to the induced emf

\[ I = \frac{E}{R}, \quad (24.13) \]

in circuits 1 and 2. Find the ratio of the currents using information given in the problem about resistance \( R \) in two cases and ratio of the emfs you found in the previous part.

• Use Eq. \((24.12)\) again to find the new ratio \( E_1/E_2 \) of the emfs taking into account the different speeds of the rods. Use Eq. \((24.13)\) to find the new ratio \( I_1/I_2 \) of the currents in the circuits due to the change in emfs. Find the ratio of the powers using

\[ P = IE \quad (24.14) \]

for the two circuits.
**Homework-Problem 24.3:** The drawing shows two surfaces that have the same area. A uniform magnetic field $\mathbf{B}$ fills the space occupied by these surfaces and is oriented parallel to the yz plane as shown. If $\theta = 38^\circ$, find the ratio $\Phi_{xz}/\Phi_{xy}$ of the magnetic fluxes that pass through the surfaces.

**Hints:**

- The magnetic flux is
  \[ \Phi = BA\cos\phi, \]  
  (24.15)

  where $B$ is magnitude of the magnetic field, $A$ is the cross-sectional area, and $\phi$ is the angle between the magnetic field and the normal to the area (area vector).

- Determine the angle $\phi$ for two cases. Use Eq. (24.15) to write expressions for $\Phi_{xz}$ and $\Phi_{xy}$. Find ratio.

**Homework-Problem 24.4:** A loop of wire has the shape shown in the drawing. The top part of the wire is bent into a semicircle of radius $r = 0.24$ m. The normal to the plane of the loop is parallel to a constant magnetic field ($\phi = 0^\circ$) of magnitude 0.86 T. What is the change $\Delta\Phi$ in the magnetic flux that passes through the loop when, starting with the position shown in the drawing, the semicircle is rotated through half a revolution?

**Hints:** The magnetic flux is changing because of the change in area.
24.3. HOMEWORK PROBLEMS

- Draw the figure after semicircle is rotated through half a revolution. Determine the change in area ($\Delta A$) between two figures.

- Use Eq. (24.15) to determine change in flux due to the change in area. ($\Delta \Phi = B\Delta A$, for $\phi = 0^\circ$)

Homework-Problem 24.5: A square loop of wire consisting of a single turn is perpendicular to a uniform magnetic field. The square loop is then re-formed into a circular loop, which also consists of a single turn and is also perpendicular to the same magnetic field. The magnetic flux that passes through the square loop is $1.9 \times 10^{-3}$ Wb. What is the flux that passes through the circular loop?

Hints:

- Use Eq. (24.15) to write expressions for flux through square loop ($\Phi_s$) and through the circular loop ($\Phi_c$).

- Find ratio $\Phi_c/\Phi_s$. Note that $B$ is same in both cases and $\phi = 0^\circ$, therefore it will only depend on the ratio of the two areas.

$$\frac{\Phi_c}{\Phi_s} = \frac{A_c}{A_s} \quad (24.16)$$

- Use the fact that the circumference of the circular loop is same as the perimeter of the square loop to determine the ratio of the areas $A_c/A_s$.

- Solve for $\Phi_c$.

Homework-Problem 24.6: A magnetic field passes through a stationary wire loop, and its magnitude changes in time according to the graph in the drawing. The direction of the field remains constant, however. There are three equal time intervals indicated in the graph: 0 – 3.0 s, 3.0 – 6.0 s, and 6.0 – 9.0 s. The loop consists of 45 turns of wire and has an area of 0.23 m$^2$. The magnetic field is oriented parallel to the normal to the loop. For purposes of this problem, this means that $\phi = 0^\circ$ in Equation (24.15).

![Figure 24.8: Homework-Problem 24.6.](image)

(a) For each interval, determine the induced emf.

(b) The wire has a resistance of 0.50 $\Omega$. Determine the induced current for the first and third intervals.
Hints:
The induced emf $\mathcal{E}$ in a coil of $N$ turns, due to change in the flux, is

$$\mathcal{E} = -N \frac{\Delta \Phi}{\Delta t}, \quad (24.17)$$

where $\Delta \Phi$ is the change in the flux and $\Delta t = t_f - t_i$ is the time interval during which the change occurred.

- Using Eq. (24.15) identify that the change in flux occurs due to change in the magnitude of the magnetic field ($\Delta B$) in this problem. Thus,

$$\Delta \Phi = (\Delta B)A. \quad (24.18)$$

Here $\Delta B = B_f - B_i$.

- Use Eqs. (24.18) and (24.17) to find induced emf $\mathcal{E}$ in each case.

- Use Eq. (24.13) to find induced current in each case.

Homework-Problem 24.7: A circular coil (1000 turns, radius = 0.02 m) is rotating in a uniform magnetic field. At $t = 0$ s, the normal to the coil is perpendicular to the magnetic field. At $t = 0.010$ s, the normal makes an angle of $\phi = 45^\circ$ with the field because the coil has made one-eighth of a revolution. An average emf of magnitude 0.040 V is induced in the coil. Find the magnitude of the magnetic field at the location of the coil.

Hints:
- Use Eq. (24.15) to identify that the change in the flux will occur due to change in the angle in this problem. Thus,

$$\Delta \Phi = BA(\cos \phi_f - \cos \phi_i), \quad (24.19)$$

where $\phi_i(\phi_f)$ is the initial(final) angle between the magnetic field and the normal to the loop.

- Use above equation in Eq. (24.17) to solve for magnitude of the magnetic field $B$.

Homework-Problem 24.8: The drawing shows a straight wire carrying a current $I$. Above the wire is a rectangular loop that contains a resistor $R$. If the current $I$ is decreasing in time, what is the direction of the induced current through the resistor $R$: left-to-right or right-to-left? If the induced current goes from left to right through the resistor, type the letters "LTR" in the box below. If the current goes from right to left through the resistor, type the letters "RTL" in the box.

Hints:
- Determine the direction of the change in the magnetic field due to the change in the current carrying wire.

- Induced magnetic field will be opposite to the direction of the change in the magnetic field (Lenz’s law).

- Use the direction of the induced magnetic field and Right Hand Rule-2 to determine the direction of the induced current through the resistor.
Homework-Problem 24.9: A generator has a square coil consisting of 660 turns. The coil rotates at 93 rad/s in a 0.31 T magnetic field. The peak output of the generator is 60.00 V. What is the length of one side of the coil?

Hints: Use

$$\mathcal{E}_0 = NBA\omega,$$  \hspace{1cm} (24.20)

to find the area $A$ of the square loop. Use area to find length $L$ of the side of the square loop.

Homework-Problem 24.10: The coil of a generator has a radius of 0.19 m. When this coil is unwound, the wire from which it is made has a length of 5.5 m. The magnetic field of the generator is 0.26 T, and the coil rotates at an angular speed of 27 rad/s. What is the peak emf of this generator?

Hints:

- Find the number of turns $N$ in the coil using the circumference of one loop and total length of the wire used in winding the coil.
- Use Eq. (24.20) to find the peak emf $\mathcal{E}_0$.

Homework-Problem 24.11: The rechargeable batteries for a laptop computer need a much smaller voltage than what a wall socket provides. Therefore, a transformer is plugged into the wall socket and produces the necessary voltage for charging the batteries. The batteries are rated at 9.0 V, and a current of 268 mA is used to charge them. The wall socket provides a voltage of 120 V.

(a) Determine the turns ratio of the transformer, $N_s/N_p$.

(b) What is the current ($I_p$) coming from the wall socket?

(c) Find the average power delivered by the wall socket ($\mathcal{P}_p$) and the average power ($\mathcal{P}_p$) sent to the batteries.

Hints:
CHAPTER 24. FARADAY INDUCTION

- Use the transformer equation
\[ \frac{V_s}{V_p} = \frac{N_s}{N_p}, \] (24.21)
to determine the turns ratio of the transformer, \( N_s/N_p \). Here, \( V_s \) is the voltage in the secondary coil and \( V_p \) is the voltage in the primary coil.

- The average power delivered to each coil is same if there is no loss of energy. Use
\[ P_p = P_s \Rightarrow I_p V_p = I_s V_s, \] (24.22)
to find current \( I_p \) in the primary coil.

- Use above equation to find the average power delivered by the wall socket \( (P_p) \) and the average power \( (P_s) \) sent to the batteries.

Homework-Problem 24.12: In a television set the power needed to operate the picture tube comes from the secondary of a transformer. The primary of the transformer is connected to a 120 V receptacle on a wall. The picture tube of the television set uses 90 W, and there is 5.5 mA of current in the secondary coil of the transformer to which the tube is connected. Find the turns ratio \( N_s/N_p \) of the transformer.

Hints:
- Find the terminal voltage \( V_s \) needed in the secondary coil to power the television using \( P_s = I_s V_s \).
- Use Eq. (24.21) to find the turns ratio \( N_s/N_p \) of the transformer.
Chapter 25

Inductance

25.1 Self inductance

A coil of wire is the simplest example of an inductor. In general, a current carrying wire, of arbitrary shape, is an inductor. The potential difference across an inductor is linearly proportional to the rate of change of current in the wire and the geometrical dependence on the shape of the wire can be absorbed into a constant. Thus, we have

\[ V = L \frac{\Delta I}{\Delta t}. \quad (25.1) \]

The geometry dependent parameter \( L \) is defined as the inductance. For a coil of length \( l \), area of crosssection \( A \), and number of turns \( N \), we have

\[ L = \frac{\mu_0 N^2 A}{l}. \quad (25.2) \]

Inductance is measured in units of Henry = Joule/Ampère\(^2\). The energy stored in an inductor is given by

\[ U = \frac{1}{2} LI^2. \quad (25.3) \]

This energy is stored in the inductor in the form of magnetic field. Show that the energy density \( u_B \) inside the inductor is

\[ u_B = \frac{1}{2\mu_0} B^2. \quad (25.4) \]

Lecture-Example 25.1: (Inductance of a solenoid.)

A solenoid of length \( l = 5.0 \text{ cm} \) and radius \( r = 0.50 \text{ cm} \) has \( N = 1000 \) turns. Determine the inductance of the solenoid. (Answer: 2.0 mH.)

25.2 RL circuit

A resistor and inductor in series constitutes a RL circuit. An inductor resists a change in current. Thus, it is the inertia of current. An obvious scenario when sharp changes in current occur in a circuit is when the switch is turned on or off. An inductor in these instances smoothen the changes in currents.
Switching on a RL circuit

A resistor and an inductor in series with a battery is governed by the equation, using Kirchoff’s law,

\[ V - IR - L \frac{\Delta I}{\Delta t} = 0. \tag{25.5} \]

We can solve this differential equation with the initial condition \( I(0) = 0 \) to yield

\[ I(t) = \frac{V}{R} \left[ 1 - e^{-\frac{t}{\tau}} \right]. \tag{25.6} \]

Thus, it takes infinite time for the current to reach its maximum value, \( I(\infty) = V/R \). Nevertheless, the rate at which the current increases is governed by \( \tau = L/R \), which is called the time constant of the RL circuit.

\[ \tau = \frac{L}{R}, \]

Figure 25.1: Switching on a RL circuit.

**Lecture-Example 25.2: (Time constant)**

Show that the current passing through a resistor at time \( t = \tau = L/R \), during the process of switching on a RL circuit, is

\[ I(\tau) = \frac{V}{R} \left( 1 - \frac{1}{e} \right) \sim 0.632 \frac{V}{R}. \tag{25.7} \]

- Evaluate the time constant \( \tau \) for the case \( R = 1.0 \text{ M\Omega} \) and \( L = 1.0 \text{ mH} \). (Answer: \( \tau = 1.0 \text{ ms} \).)

25.3 LC circuit

An inductor and a capacitor in series constitutes a LC circuit. A capacitor stores energy in the form electric field and an inductor stores energy in the form of magnetic field. Thus, an ideal LC circuit leads to oscillations in current, corresponding to the oscillations in the electric and magnetic energy.

An inductor and a capacitor in series is governed by the equation, using Kirchoff’s law,

\[ \frac{\Delta I}{\Delta t} = -\frac{Q}{LC}. \tag{25.8} \]

We can solve this differential equation with the initial condition \( Q(0) = Q_0 \) to yield

\[ Q(t) = Q_0 \cos \omega t, \tag{25.9} \]

where the angular frequency of oscillations is given by

\[ \omega = \frac{1}{\sqrt{LC}}. \tag{25.10} \]
25.4 Homework problems

**Homework-Problem 25.1:** The earth’s magnetic field, like any magnetic field, stores energy. The maximum strength of the earth’s field is about $7.0 \times 10^{-5}$ T. Find the maximum magnetic energy stored in the space above a city if the space occupies an area of $8.00 \times 10^8$ m$^2$ and has a height of 800 m.

**Hints:**

The magnetic energy per unit volume stored in a magnetic field $B$ is

$$\frac{E_{\text{mag}}}{V} = \frac{B^2}{2\mu_0}, \quad (25.11)$$

where $V$ is the volume of the space and $\mu_0$ is the permeability of the free space.

**Homework-Problem 25.2:** The current through a 5.6 mH inductor varies with time according to the graph shown in the drawing. What is the average induced emf during the time intervals?

![Figure 25.2: Homework-Problem 25.2.](image)

(a) 0 – 2.0 ms

(b) 3.0 – 5.0 ms

(c) 5.0 – 9.0 ms

**Hints:**

Self-induced emf in an inductor due to the varying current is

$$\mathcal{E} = -L \frac{\Delta I}{\Delta t}, \quad (25.12)$$

Here $L$ is the inductance, $\Delta I$ is the change in current during time $\Delta t$ through the inductor. ($\Delta I/\Delta t$ is known as the rate of change of current.)

**Homework-Problem 25.3:** A constant current of $I = 15$ A exists in a solenoid whose inductance is $L = 30.1$ H. The current is then reduced to zero in a certain amount of time.
(a) If the current goes from 15 to 0 A in a time of 75 ms, what is the emf $E$ induced in the solenoid?

(b) How much electrical energy is stored in the solenoid? (Consider the initial energy stored.)

(c) At what rate $P$ must the electrical energy be removed from the solenoid when the current is reduced to 0 A in a time of 75 ms? Note that the rate at which energy is removed is the power.

Hints:
- Use Eq. (25.12) to find the induced emf.
- The electrical energy stored in the solenoid is
  \[ E = \frac{1}{2} LI^2. \]  \hspace{1cm} (25.13)
- Power is the rate of change of energy:
  \[ P = \frac{\Delta E}{\Delta t}. \]  \hspace{1cm} (25.14)
  Here $\Delta E$ is the change in energy in the solenoid during time interval $\Delta t$.

Homework-Problem 25.4: A coil has an inductance of 6.00 mH, and the current in it changes from 0.200 A to 1.50 A in a time interval of 0.300 s. Find the magnitude of the average induced emf in the coil during this time interval.

Hints:
- Use Eq. (25.12). (Magnitude is the absolute value without the sign.)

Homework-Problem 25.5: A 1.75 H inductor carries a steady current of 0.480 A. When the switch in the circuit is thrown open, the current is effectively zero in 10.0 ms. What is the average induced emf in the inductor during this time?

Hints:
- Use Eq. (25.12).
Chapter 26

Electromagnetic waves

26.1 Maxwell’s equations

Let us analyse the Ampère law for a RC circuit, while the capacitor is charging. Using Ampère’s law in Fig. 26.1, and using the ambiguity in defining the surface bounded by a curve, we deduce

\[
\sum \vec{B} \cdot \Delta \vec{l} = \begin{cases} 
\mu_0 I, & \text{for surface } S_1, \\
0, & \text{for surface } S_2.
\end{cases}
\] (26.1)

This apparent contradiction was removed by Maxwell by restating the Ampère law as

\[
\sum \vec{B} \cdot \Delta \vec{l} = \mu_0 I + \mu_0 \varepsilon_0 \frac{\Delta \Phi_E}{\Delta t},
\] (26.2)

which implies that a rate of change of the electric flux can also generate a magnetic field.

Thus, the four independent laws that govern the electric and magnetic field in a region of space, in integral form, are the following.

\[
\sum \vec{E} \cdot \Delta \vec{A} = \frac{Q_{en}}{\varepsilon_0} \quad \text{(Gauss’s law for } \vec{E})
\] (26.3a)

\[
\sum \vec{B} \cdot \Delta \vec{A} = 0 \quad \text{(Gauss’s law for } \vec{B})
\] (26.3b)

\[
\sum \vec{E} \cdot \Delta \vec{l} = \frac{\Delta \Phi_B}{\Delta t} \quad \text{(Faraday’s law)}
\] (26.3c)

\[
\sum \vec{B} \cdot \Delta \vec{l} = \mu_0 \varepsilon_0 \frac{\Delta \Phi_E}{\Delta t} + \mu_0 I \quad \text{(Ampère’s law)}
\] (26.3d)
The above four equations are collectively called the Maxwell equations. The symmetry in the electric and magnetic effects is striking in the above equations, which would have been complete if not for the absence of magnetic charges and magnetic currents. There is no conclusive experimental observation of magnetic charges.

26.2 Electromagnetic waves

The Maxwell equations imply that, in a region of space where there are no charges and currents, the electric and magnetic fields satisfy the wave equations

\[
\frac{\Delta^2 \vec{E}}{\Delta z^2} = \frac{1}{c^2} \frac{\Delta^2 \vec{E}}{\Delta t^2},
\]

(26.4a)

\[
\frac{\Delta^2 \vec{B}}{\Delta z^2} = \frac{1}{c^2} \frac{\Delta^2 \vec{B}}{\Delta t^2},
\]

(26.4b)

where the speed of these waves, called the speed of light, is

\[
c = \frac{1}{\sqrt{\mu_0 \varepsilon_0}}.
\]

(26.5)

The meter, in SI units, is defined as the distance travelled by light in vacuum in \(1/299\,792\,458\) of a second. As a consequence, the speed of light in vacuum, in SI units, is expressed as a whole number,

\[
c = 299\,792\,458 \frac{\text{m}}{\text{s}}.
\]

(26.6)

These electromagnetic waves, which are oscillations of the electric and magnetic fields in space and time, can sustain each other.

**Properties of electromagnetic waves in vacuum**

1. The wave nature stipulates the relation between the wavelength \(\lambda\), frequency \(f\), and speed \(c\) of the wave,

\[
c = \lambda f.
\]

(26.7)

The time period \(T = 1/f\), and the wavevector \(k = 2\pi/\lambda\), are related quantities.

2. The electromagnetic energy density is given by

\[
u = \frac{1}{2} \varepsilon_0 E^2 + \frac{1}{2\mu_0} B^2.
\]

(26.8)

The flux of the electromagnetic energy density, a measure of the flow rate of electromagnetic energy per unit area, is given by the Poynting vector

\[
\vec{S} = \frac{1}{\mu_0} \vec{E} \times \vec{B}.
\]

(26.9)

The electromagnetic momentum density is given by

\[
\vec{G} = \frac{1}{c^2} \vec{S}.
\]

(26.10)

3. The Maxwell equations constraint the directions of the electric field, the magnetic field, and the direction of propagation to be mutually perpendicular,

\[
\vec{E} \times \vec{B} = \hat{k} c \mu_0 u, \quad \vec{E} \cdot \vec{B} = 0.
\]

(26.11)

Further, we have

\[
E = cB.
\]

(26.12)
26.3 Doppler effect

The Doppler formula for the apparent frequency measured by the observer, due to relative motion of the observer and source with respect to the medium, is given by

\[ f' = f \left( \frac{v_0 \pm v_d}{v_0 \mp v_s} \right), \quad (26.13) \]

where \( v_0 \) is the speed of the wave, \( v_s \) is the speed of the source, and \( v_d \) is the speed of the detector. The non-relativistic Doppler formula for light, which does not take care of time dilation of special relativity, and applicable to \( \mathcal{O}(u/c)^2 \), is

\[ f' = f \left( 1 \pm \frac{|u|}{c} \right), \quad (26.14) \]

where \( u = v_s - v_d \) is the relative velocity of the source with respect to the detector.

---

**Lecture-Example 26.3:** (Radar speed gun)
A radar speed gun is a device that measures the relative speed of an object with respect to the device using the Doppler effect. Consider the case of a police car moving at 30.0 m/s chasing a speeder moving at 40.0 m/s. The radar speed gun in the police car emits a radio signal with a frequency of 32.00 GHz. Determine the difference in the emitted and detected frequencies of the radio signal as measured, by the radar gun after it has been reflected off the speeding car. (Answer: 2135 Hz.)
26.4 Polarization of an electromagnetic wave

The electric and magnetic field, the physical quantities that are oscillating in an electromagnetic wave, are vectors. When projected along a certain direction vectors collapse into their respective vector component along the direction, determined by the property of the scalar product of vectors. The polarization of a vector is determined by the direction of the electric field of the electromagnetic wave. A polarizer is a device that projects the electric field along the direction of the transmission axis specific to the polarizer. The intensity of an electromagnetic wave is proportional to the square of the electric field. Thus, the intensity of an electromagnetic wave after passing through a polarizer is related to the intensity of the original wave by the relation

\[ I' = \begin{cases} \frac{1}{2}I_0, & \text{for unpolarized incident wave}, \\ I_0 \cos^2 \theta, & \text{for polarized incident wave}, \end{cases} \]  

(26.15)

where \( \theta \) is the relative orientation of the incident polarized wave with respect to the transmission axis of the polarizer. The factor of half for the case of unpolarized light is the average of \( \cos^2 \theta \) over angle \( \theta \).

Lecture-Example 26.4:

Figure 26.2 shows three polarizers in series. The angles \( \theta_A, \theta_B, \) and \( \theta_C \), represent the angles the respective transmission axis of the polarizers \( A, B, \) and \( C \), makes with the vertical. Consider a beam of unpolarized light of intensity \( I_0 \) incident on the polarizer \( A \). (Express your answers in terms of \( I_0 \).)

\[ \theta_A = 0^\circ \quad \theta_B = 30^\circ \quad \theta_C = 90^\circ \]

- What is the intensity of the transmitted beam after it passes the polarizer \( A \) and before it passes polarizer \( B \)? (Answer: \( I_A = I_0/2 \).) What is the intensity of the transmitted beam after it passes the polarizer \( B \) and before it passes polarizer \( C \)? (Answer: \( I_B = 3I_0/8 \).) What is the intensity of the transmitted beam after it passes the polarizer \( C \)? (Answer: \( I_C = 3I_0/32 \).)

- In the absence of polarizer \( B \), what is the intensity of the transmitted beam after it passes the polarizer \( C \)? (Answer: \( I_C = 0 \).)

26.5 Homework problems

Homework-Problem 26.1:

(a) Neil A. Armstrong was the first person to walk on the moon. The distance between the earth and the moon is \( 3.85 \times 10^8 \) m. Find the time it took for his voice to reach the earth via radio waves.
(b) Someday a person will walk on Mars, which is $5.6 \times 10^{10}$ m from the earth at the point of closest approach. Determine the minimum time that will be required for a message from Mars to reach the earth via radio waves.

**Hints:**

*Radio waves travels with speed of light.*

---

**Homework-Problem 26.2:** In astronomy, distances are often expressed in light-years. One light-year is the distance traveled by light in one year. The distance to Alpha Centauri, the closest star other than our own sun that can be seen by the naked eye, is about 4.5 light-years. Express this distance in meters.

**Hints:**

*Unit conversion.*

---

**Homework-Problem 26.3:** In a dentist’s office, an X-ray of a tooth is taken using X-rays that have a frequency of $9.07 \times 10^{18}$ Hz. What is the wavelength in vacuum of these X-rays?

**Hints:**

Use

$$c = f\lambda.$$  \hspace{1cm} (26.16)

Here $c$ is the speed of light, $\lambda$ is the wavelength, and $f$ is the frequency of the wave.

---

**Homework-Problem 26.4:** FM radio waves have frequencies between 88.0 and 108.0 MHz. Determine the range of wavelengths for these waves. (Enter your answers from smallest to largest.)

**Hints:**

Use Eq. (26.16) to find the smallest and the largest wavelength for given frequencies.

---

**Homework-Problem 26.5:** The figure below illustrates Michelson’s setup for measuring the speed of light with the mirrors placed on Mt. San Antonio and Mt. Wilson in California, which are 35 km apart. Using a value of $3.00 \times 10^8$ m/s for the speed of light, find the minimum angular speed (in rev/s) for the rotating mirror.

**Hints:**

- Find the time it takes light for the round trip. *You can approximate total distance travelled by twice the straight distance as two mirrors are far apart.*

- The rotating mirror rotates $\frac{1}{8}$th of the full revolution during this time.

- Determine the angular speed using time required for one full revolution. *Your answer would be in rev/sec.* *(Not in rad/sec.)*
Homework-Problem 26.6: Two astronauts are 1.6 m apart in their spaceship. One speaks to the other. The conversation is transmitted to earth via electromagnetic waves. The time it takes for sound waves to travel at 343 m/s through the air between the astronauts equals the time it takes for the electromagnetic waves to travel to the earth. How far away from the earth is the spaceship?

Hints:
Find the time it takes for sound waves to travel the distance between the two astronauts. Use it to find distance of spaceship from the earth. (Electromagnetic waves travel with speed of light.)

Homework-Problem 26.7: The maximum strength of the magnetic field in an electromagnetic wave is $3.3 \times 10^{-6}$ T. What is the maximum strength of the wave’s electric field?

Hints:
Use $E = cB$.

Homework-Problem 26.8: The microwave radiation left over from the Big Bang explosion of the universe has an average energy density of $4. \times 10^{-14}$ J/m³. What is the rms value of the electric field of this radiation?

Hints:
Use $u = \varepsilon_0E^2$.

Homework-Problem 26.9: A distant galaxy emits light that has a wavelength of 500.7 nm. On earth, the wavelength of this light is measured to be 503.7 nm.

(a) Decide whether this galaxy is approaching or receding from the earth.
(b) Find the speed of the galaxy relative to the earth.

**Hints:**

- Determine the source frequency \( f_s \) emitted by the galaxy and the observed frequency \( f_o \) observed on the earth using Eq. (26.16).

- **Is observed frequency less than or greater than the source frequency?**

- Now use
  \[
  \frac{f_o}{f_s} = \left(1 \pm \frac{u}{c}\right),
  \]
  (26.17)
  where \( u \) is the velocity of the galaxy (source), to determine which sign (plus or minus) shall satisfy your answer to above question.
  + sign corresponds to the approaching galaxy and − sign corresponds to the receding galaxy.

- Use Eq. (26.17) to solve for velocity of the galaxy \( u \) (using correct sign).

---

**Homework-Problem 26.10:** A speeder is pulling directly away and increasing his distance from a police car that is moving at 27 m/s with respect to the ground. The radar gun in the police car emits an electromagnetic wave with a frequency of \( 9.00 \times 10^9 \) Hz. The wave reflects from the speeder’s car and returns to the police car, where its frequency is measured to be 326 Hz less than the emitted frequency. Find the speeder’s speed with respect to the ground.

**Hints:**

- Speeder will observe a shifted frequency of the electromagnetic wave emitted by the police car. It is then reflected back to the police car, which again see a shift in the frequency.

- Use Eq. (26.17) twice to get
  \[
  \frac{f_2}{f_1} = \left(1 - \frac{u}{c}\right)^2,
  \]
  (26.18)
  where \( f_1 \) is the frequency emitted by the police car and \( f_2 \) is the frequency observed by the police car. Above relation can be simplified to obtain
  \[
  \frac{\Delta f}{f_1} = \frac{2u}{c},
  \]
  (26.19)
  where \( \Delta f = f_1 - f_2 \) and we have neglected \((u/c)^2\) since \( u \ll c \).

- Solve for relative velocity \( u \) of the speeder with respect to the police car using above expression. Find the velocity of the speeder with respect to the ground using information about the velocity of the police car.

---

**Homework-Problem 26.11:** The drawing shows three situations-A, B, and C-in which an observer and a source of electromagnetic waves are moving along the same line. In each case the source emits a wave that has a frequency of \( 4.57 \times 10^{14} \) Hz. The arrows in each situation denote velocity vectors of the observer and source relative to the ground and have the magnitudes indicated \((v \text{ or } 2v)\), where the speed \( v \) is \( 1.25 \times 10^6 \) m/s. Calculate the observed frequency in each of the three cases.
Hints:
Use Eq. (26.17) with correct sign to solve for observed frequency \( f_o \) in each case.

**Homework-Problem 26.12:** For each of the three sheets of polarizing material shown in the drawing, the orientation of the transmission axis is labeled relative to the vertical. The incident beam of light is unpolarized and has an intensity of 1000.0 W/m\(^2\). What is the intensity of the beam transmitted through the three sheets when \( \theta_1 = 19.0^\circ \), \( \theta_2 = 55.5^\circ \) and \( \theta_3 = 100.0^\circ \)?

Hints:
The intensity coming out of the first polarizer is halved and next ones, sequentially, are given by
\[
I' = I \cos^2 \theta,
\]
where \( \theta \) is the change in orientation of the polarizers.

**Homework-Problem 26.13:** The drawing shows four sheets of polarizing material, each with its transmission axis oriented differently. Light that is polarized in the vertical direction is incident from the left and has an average intensity of 28 W/m\(^2\). Determine the average intensity of the light that emerges on the right in the drawing (a) when sheet A alone is removed, (b) when sheet B alone is removed, (c) when sheet C alone is removed, and (d) when sheet D alone is removed.

Hints:
The intensity coming out of the first polarizer is halved and next ones, sequentially, are given by
\[
I' = I \cos^2 \theta,
\]
where \( \theta \) is the change in orientation of the polarizers.
26.5. HOMEWORK PROBLEMS

Figure 26.6: Homework-Problem 26.13.
Part III

Optics
Chapter 27

Ray Optics: Reflection

Visible light is an electromagnetic wave, oscillations of electric and magnetic fields in space and time. The wavelength of visible light is in the range of $0.400 - 0.700 \mu\text{m}$. When the size of irregularities at the interface of two media is smaller than the wavelength of visible light, it is a good approximation to treat the electromagnetic wave by rays of light, along the direction of propagation of the waves, which are perpendicular to the surfaces formed by the wave fronts. The study of propagation of light, in this straight line approximation, is called ray optics.

Visible light, and other electromagnetic waves, cannot penetrate into a perfect conductor, because the electric field has to be zero inside a perfect conductor. A metal, like gold and silver, is a perfect conductor to a good approximation. The surface of a metal is naturally smooth. The surface of a perfect conductor will be called a mirror. The mirrors we typically find in daily use, consists of a slab of glass with a coating of metal on one of the surfaces of the slab.

27.1 Law of reflection

Propagation of light at the interface of a medium and a mirror is governed by the law of reflection that states that the angle of incidence is equal to the angle of reflection.

![Figure 27.1: A ray of light reflected by a mirror.](image)

Image formation as a perception of our eye

Our eye extrapolates two or more rays of light and the point of intersection of these rays is perceived as a source or image. If the light passes through the point of intersection of the extrapolated rays, it is perceived as a real image. Image formed by a overhead projector is a real image. If the light does not pass through the point of intersection of the extrapolated rays, it is perceived as a virtual image. Image formed by a bathroom mirror is a virtual image.
Lecture-Example 27.1: (Optimal mirror placement)
Your height is $h$. The vertical distance between your eye and top of head is $h_1$, and between your eye and toe is $h_2$.

- What is the minimum height $y = y_1 + y_2$ of a mirror you need to place on a vertical wall in which you can see your complete image?
- Does your answer depend on how far away you stand from the mirror?

Lecture-Example 27.2:
Given $\alpha = 30.0^\circ$, in Figure 27.4. Show that $\theta = 2\alpha$. 
27.2 Spherical mirrors

When the surface of a mirror is part of a sphere, it is called a spherical mirror. If the inner side of the part of sphere forms the reflecting surface, it is called a concave mirror. If the outer side of the part of sphere forms the reflecting surface, it is called a convex mirror. The center of the sphere, of which the mirror is a part, is called the center of curvature. The radius of this sphere is called the radius of curvature. A line passing through the center of curvature and the center of the mirror will be defined to the optical axis, the direction being that of a light ray. The focal point is the point half way between the center of curvature and center of mirror, and the corresponding distance is the focal length,

\[ f = \frac{R}{2}. \]  

(27.1)

The sign conventions, and the related terminologies, is summarized in Figure 27.5.

Mirror formula

Using the law of reflection and the geometry of a circle we can deduce the mirror formula

\[ \frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f}, \]  

(27.2)

and the expression for magnification,

\[ m = \frac{h_i}{h_o} = -\frac{d_i}{d_o}. \]  

(27.3)
Lecture-Example 27.3: (Plane mirror)
A plane mirror has an infinite radius of curvature. Using the mirror formula, conclude that the image distance
is equal to the negative of the object distance, \( d_i = -d_o \). Thus, deduce that, the image formed when you stand
in front of a plane mirror is virtual and upright.

Lecture-Example 27.4: (Concave mirror)
An object of height \( h_o = 1.0 \text{ cm} \) is placed upright at a distance \( d_o \) in front of a concave mirror. The mirror’s
focal length is \( f = +10.0 \text{ cm} \).
- Let \( d_o = +30.0 \text{ cm} \). Calculate the image distance. (Answer: \( d_i = +15 \text{ cm} \).) What is the magnification?
Answer: \( m = -0.50 \). Is the image real or virtual? Is the image inverted or upright? Verify your results
using a ray diagram drawn.
- Repeat for \( d_o = +20.0 \text{ cm} \). (Answer: \( d_i = +20.0 \text{ cm}, m = -1.0 \).)
- Repeat for \( d_o = +15.0 \text{ cm} \). (Answer: \( d_i = +30.0 \text{ cm}, m = -2.0 \).)
- Repeat for \( d_o = +10.0 \text{ cm} \). (Answer: \( d_i \to \pm \infty \text{ cm}, m \to \pm \infty \).)
- Repeat for \( d_o = +5.0 \text{ cm} \). (Answer: \( d_i = -10.0 \text{ cm}, m = +2.0 \).)

Lecture-Example 27.5: (Convex mirror)
An object of height \( h_o = 1.0 \text{ cm} \) is placed upright at a distance \( d_o \) in front of a convex mirror. The mirror’s
focal length is \( f = -10.0 \text{ cm} \).
- Let \( d_o = +30.0 \text{ cm} \). Calculate the image distance. (Answer: \( d_i = -7.5 \text{ cm} \).) What is the magnification?
Answer: \( m = +0.25 \). Is the image real or virtual? Is the image inverted or upright? Verify your results
using a ray diagram drawn.
- Verify that the image is always virtual, upright, and diminished.
- Rear view mirrors on automobiles are convex mirrors. Understand the following warning statement re-
garding rear view mirrors, “Objects in mirror are closer than they appear”.

27.3 Homework problems

Homework-Problem 27.1: You are trying to photograph a bird sitting on a tree branch, but a tall hedge
is blocking your view. However, as the drawing shows, a plane mirror reflects light from the bird into your
camera. If \( x = 4.4 \text{ m} \) and \( y = 4.6 \text{ m} \) in the drawing. For what distance must you set the focus of the camera
lens in order to snap a sharp picture of the bird’s image?

Hints:
- The (virtual) image of the bird forms 2.1 cm behind the mirror at the same height \( y \). Draw this image.
- Focus of the camera lens must be set for the distance between the virtual image and the camera. Use
geometry of a right triangle to find this distance.
Homework-Problem 27.2: Two plane mirrors are separated by 120°, as the drawing illustrates. If a ray strikes mirror $M_1$ at a $\theta_1 = 63°$ angle of incidence, at what angle $\theta_2$ does it leave mirror $M_2$?

Hints:
Use law of reflection and geometry of triangle to find the missing angles.

Homework-Problem 27.3: The drawing shows a laser beam shining on a plane mirror that is perpendicular to the floor. The beam’s angle of incident is 27.4°. The beam emerges from the laser at a point that is 1.10 m from the mirror and 1.80 m above the floor. After the reflection, how far from the base of the mirror does the beam strike the floor?

Hints:
- The angle of reflection is same as angle of incidence. Draw the reflected ray (showing where it hits the floor).
- Use the (upper) right triangle and length of the plane mirror to determine the height where the laser beam hits the plane mirror.
• Use the above information and (lower) right triangle formed by mirror, floor, and reflected ray to find the distance where reflected ray hits the floor.

Homework-Problem 27.4: Two plane mirrors are facing each other. They are parallel, 6 cm apart, and 25 cm in length, as the drawing indicates. A laser beam is directed at the top mirror from the left edge of the bottom mirror. What is the smallest angle of incidence with respect to the top mirror, such that the laser beam hits the mirrors in each way?

a) hits only one of the mirrors
b) hits each mirror only once

Hints:
• The smallest angle of incidence corresponds to the situation where the reflected ray leaves the setup barely touching the edge.
• Draw the figure when incident ray hits only one mirror and leaves barely touching the other mirrors.
• Determine the distance where the incident ray hits the mirror from the left side.
• Next draw the normal to the mirror where incident ray hits. Angle of incidence is the angle between the normal and the incident ray. Use the geometry to determine this angle.
• Follow the above steps for the second part.
Homework-Problem 27.5: When an object is located very far away from a convex mirror, the image of the object is 12.0 cm behind the mirror. Using a ray diagram drawn to scale, determine where the image is located when the object is placed 2.0 cm in front of the mirror. Note that the mirror must be drawn to scale also. In your drawing, assume that the height of the object is 3.0 cm.

Hints:

Homework-Problem 27.6: An object is placed 9 cm in front of a concave mirror whose focal length is 20 cm. The object is 3.05 cm tall. Using a ray diagram drawn to scale, measure the location and the height of the image. The mirror must be drawn to scale.

Hints:

Homework-Problem 27.7: A 5.0 cm-high object is situated 16.0 cm in front of a concave mirror that has a radius of curvature of 12.0 cm. Use a ray diagram drawn to scale, measure the following. The mirror must be drawn to scale.

(a) the image distance (include the sign)
(b) the height of the image

Hints:

Homework-Problem 27.8: A convex mirror has a focal length of $-33.0$ cm. A 12.0 cm-tall object is located 39.0 cm in front of this mirror.

(a) Using a ray diagram drawn to scale, determine the location of the image. Note that the mirror must be drawn to scale.

(b) Using a ray diagram drawn to scale, determine the size of the image. (Use a negative sign for an inverted image, positive for upright.)

Hints:

Homework-Problem 27.9: A small statue has a height of 2.9 cm and is placed in front of a concave mirror. The image of the statue is inverted, 1.7 cm tall, and located 10 cm in from the mirror. Find the focal length of the mirror.

Hints:
- Use magnification relation

$$m = \frac{h_i}{h_o} = -\frac{d_i}{d_o}$$

(27.4)
to determine the magnification using the heights of the object ($h_o$) and the image ($h_i$). Take care of the sign for the height of the inverted image.
• Use the mirror equation
\[ \frac{1}{d_i} + \frac{1}{d_o} = \frac{1}{f} \]  
(27.5)
and the relation \( d_o = -d_i/m \) (from Eq. (27.4)) to obtain
\[ \frac{1}{d_i}(1 - m) = \frac{1}{f}. \]  
(27.6)

• Use magnification \( m \) and image distance \( d_i \) to solve for the focal length \( f \).

**Homework-Problem 27.10:** The outside mirror on the passenger side of a car is convex and has a focal length of \(-7.5\) m. Relative to this mirror, a truck traveling in the rear has an object distance of \(15\) m.

(a) Find the image distance of the truck.

(b) Find the magnification of the mirror.

**Hints:**
• Use mirror equation, Eq. (27.5) to find the image distance \( d_i \).
• Use object distance \( d_o \) and image distance \( d_i \) in Eq. (27.4) to find the magnitude. *Keep track of the signs.*

**Homework-Problem 27.11:** A dentist’s mirror is placed \(2.7\) cm from a tooth. The enlarged image is located \(6.4\) cm behind the mirror.

(a) What kind of mirror (plane, concave, or convex) is being used?

(b) Determine the focal length of the mirror.

(c) What is the magnification?

(d) How is the image oriented relative to the object?

**Hints:**
• Note that image is formed behind the mirror (virtual) and is enlarged. This occurs when an object is placed within the focal length distance from a concave mirror. *Draw a ray diagram to verify this.*
• Use Eq. (27.5) to find the focal length of the mirror. *Take care of the negative sign for the virtual image distance.*
• Use Eq. (27.4) to find the magnification.
• If the sign of magnification is positive then the object and the image are in same direction.
Homework-Problem 27.12: A candle is placed 29.7 cm in front of a convex mirror. When the convex mirror is replaced with a plane mirror, the image moves 7.0 cm farther away from the mirror. Find the focal length of the convex mirror.

Hints:

• Note that both plane mirror and convex mirror form (virtual) image behind the mirror.

• The object distance is same as the image distance for the plane mirror.

• Use information given in the problem with the above facts to determine the image distance for the case of the convex mirror.

• Use Eq. (27.5) to find the focal length. *(Take care of the sign of the object distance for the virtual image.)*
Chapter 28

Ray optics: Refraction

28.1 Index of refraction

Electromagnetic waves travel at the speed of light $c$ in vacuum. But, they slow down in a medium. The refractive index of a medium

$$n = \frac{c}{v} \tag{28.1}$$

is a measure of the speed of light $v$ in the medium. Refractive index of a medium is always greater than or equal to unity. The speed of light in a medium varies with the color of light. Thus, for the same medium, the refractive index changes with the color of light, a phenomena called dispersion.

28.2 Law of refraction

The law of refraction, or Snell’s law, relates the angle of incidence and angle of refraction at the interface of two mediums,

$$n_1 \sin \theta_1 = n_2 \sin \theta_2. \tag{28.2}$$

It can be derived using Fermat’s principle that states that light takes the path of least time. As a consequence, a ray light bends towards the normal when it goes from a denser to a rarer medium, and vice versa.

Lecture-Example 28.1: (Apparent depth)

Determine the apparent depth $h'$ of a swimming pool of real depth $h$.

- Show that

$$h' \tan \theta_1 = h \tan \theta_2. \tag{28.3}$$

Then, show that, for small angles we have

$$h' = \frac{n_1}{n_2}h. \tag{28.4}$$

Evaluate the apparent depth for $h = 2.0 \text{ m}$, $n_1 = 1.0$, and $n_2 = 1.33$. (Answer: $h' = 1.5 \text{ m}$.)

Table 28.1: Orders of magnitude (refractive index).
CHAPTER 28. RAY OPTICS: REFRACTION

Lecture-Example 28.2: (Prism)
Light travels through a prism made of glass ($n = 1.5$) as shown in Figure 28.2. Given $\alpha = 50^\circ$ and $i_1 = 45^\circ$. Determine the angle of deviation $\delta$.

28.3 Total internal reflection

When light passes from a denser to a rarer medium, it bends away from the normal. As a consequence, there exists a critical angle beyond which there is no refraction. The critical angle is determined using $\theta_2 = 90^\circ$, for $n_1 > n_2$.

$$n_1 \sin \theta_c = n_2.$$  \hfill (28.5)

Lecture-Example 28.3:
The index of refraction of benzene is 1.80. Determine the critical angle for total internal reflection at a benzene-air interface. (Answer: $\theta_c = 33.8^\circ$.)

Lecture-Example 28.4: (Examples)

- Fibre optic cable.
- Optical phenomenon called mirage.
28.4 Thin spherical lens

When the surface of the interfaces enclosing a medium is spherical in shape, on both sides, it is called a thin spherical lens. The focal length of a thin spherical lens is given in terms of the radius of curvatures of the two interfaces, $R_1$ and $R_2$,

$$\frac{1}{f} = (n - 1) \left[ \frac{1}{R_1} - \frac{1}{R_2} \right]. \tag{28.6}$$

The sign conventions, and the related terminologies, is summarized in Figure 28.3.

![Figure 28.3: Sign conventions for spherical lenses.](image)

**Lecture-Example 28.5:** (Convex lens)

An object of height $h_o = 1.0 \text{ cm}$ is placed upright at a distance $d_o$ in front of a convex lens. The lens’ focal length is $f = +10.0 \text{ cm}$.

- Let $d_o = +30.0 \text{ cm}$. Calculate the image distance. (Answer: $d_i = +15.0 \text{ cm}$.) What is the magnification? (Answer: $m = -0.50$.) Is the image real or virtual? Is the image inverted or upright? Verify your results using a ray diagram drawn.

- Repeat for $d_o = +20.0 \text{ cm}$. (Answer: $d_i = +20.0 \text{ cm}, m = -1.0$.)

- Repeat for $d_o = +15.0 \text{ cm}$. (Answer: $d_i = +30.0 \text{ cm}, m = -2.0$.)

- Repeat for $d_o = +10.0 \text{ cm}$. (Answer: $d_i \to \pm \infty \text{ cm}, m \to \pm \infty$.)

- Repeat for $d_o = +5.0 \text{ cm}$. (Answer: $d_i = -10.0 \text{ cm}, m = +2.0$.)
Lecture-Example 28.6: (Concave lens)
An object of height \( h_o = 1.0 \text{ cm} \) is placed upright at a distance \( d_o \) in front of a concave lens. The lens’ focal length is \( f = -10.0 \text{ cm} \).

- Let \( d_o = +30.0 \text{ cm} \). Calculate the image distance. (Answer: \( d_i = -7.5 \text{ cm} \).) What is the magnification? (Answer: \( m = +0.25 \).) Is the image real or virtual? Is the image inverted or upright? Verify your results using a ray diagram drawn.
- Verify that the image is always virtual, upright, and diminished.

28.5 Homework problems

Homework-Problem 28.1: A plate glass window \((n = 1.5)\) has a thickness of \(2.00 \times 10^{-3} \text{ m} \). How long does it take light to pass perpendicularly through the plate?

Hints:
Find the speed of light, \( v \), in the glass using
\[
n = \frac{\text{Speed of light in vacuum}}{\text{Speed of light in the material}} = \frac{c}{v}.
\] (28.9)

Find the time taken by the light to pass through the glass window using speed and thickness.

Homework-Problem 28.2: The drawing shows four different situations in which a light ray is traveling from one medium into another. In some of the cases, the refraction is not shown correctly. For cases (a), (b), and (c), the angle of incidence is \(32^\circ\) and for case (d), the angle of incidence is \(0^\circ\).

![Figure 28.4: Homework-Problem 28.2.](image)

Determine the angle of refraction in each case.

Hints:
28.5. HOMEWORK PROBLEMS

- Use Snell’s law of refraction:
  \[ n_1 \sin \theta_1 = n_2 \sin \theta_2 \]  
  (28.10)
to find angle of refraction in each case.
- Note that angles \( \theta_{1,2} \) are angle(s) between the light ray and perpendicular to the surface in the respective medium.

### Homework-Problem 28.3:
The drawing shows a coin resting on the bottom of a beaker filled with an unknown liquid. A ray of light from the coin travels to the surface of the liquid and is refracted as it enters into the air. A person sees the ray as it skims just above the surface of the liquid. How fast is the light traveling in the liquid? (Let \( x = 5.40 \) cm and \( y = 5.98 \) cm.)

![Figure 28.5: Homework-Problem 28.3.](image)

**Hints:**
- Light ray emerges parallel to the surface, which means angle of refraction is \( \theta_2 = 90^\circ \).
- Find the angle of incidence, \( \theta_1 \), light ray makes with the perpendicular to the surface inside the medium using geometry of the right triangle.
- Use Snell’s Law (Eq. (28.10)) to determine the refractive index, \( n_1 \), of the material. (\( n_2 \) is the refractive index for air.)
- Use Eq. (28.9) to find the velocity of light in the medium.

### Homework-Problem 28.4:
The drawing shows a ray of light traveling through three materials whose surfaces are parallel to each other. The refracted rays (but not the reflected rays) are shown as the light passes through each material. A ray of light strikes the \( a-b \) interface at a 50.0° angle of incidence. The index of refraction of material \( a \) is \( n_a = 1.20 \). The angles of refraction in materials \( b \) and \( c \) are, respectively, 44.9° and 52.5°. Find the indices of refraction in these two media.

**Hints:**
- Use Snell’s Law (Eq. (28.10)) for both interfaces.
- Use geometry and angle of refraction at interface \( a-b \) to determine the angle of incidence at the interface \( b-c \).
Homework-Problem 28.5: A glass is half-full of water, with a layer of vegetable oil \((n = 1.47)\) floating on top. A ray of light traveling downward through the oil is incident on the water at an angle of \(50.2^\circ\). Determine the critical angle for the oil-water interface.

Decide whether the ray will penetrate into the water.

Hints:

- Critical angle, \(\theta_c\), is the angle of incidence for which the angle of refraction at an interface is \(90^\circ\). Using Eq. \((28.10)\) obtain

\[
\sin \theta_c = \frac{n_2}{n_1}.
\]

\(n_2\) is the refractive index of water. Solve for \(\theta_c\).

- Compare it with the given angle of incidence. Light is totally internally reflected for any angle of incidence larger than the critical angle, which means no refraction at all.

Homework-Problem 28.6: A ray of light is traveling in glass and strikes a glass/liquid interface. The angle of incidence is \(59.0^\circ\), and the index of refraction of glass is \(n = 1.50\).

(a) What must be the index of refraction of the liquid such that the direction of the light entering the liquid is not changed?

(b) What is the largest index of refraction that the liquid can have, so that none of the light is transmitted into the liquid and all of it is reflected back into the glass?

Hints:

- Direction of light won’t change if the angle of incidence is equal to the angle of refraction. Determine the refractive index of the liquid using Eq. \((28.10)\) for this case.

- For no refraction the given angle of incident should be the critical angle for the glass/liquid interface. Use Eq. \((28.11)\) to find the index of refraction that the liquid can have for the given angle of incidence.
Homework-Problem 28.7: The drawing shows a crystalline quartz slab with a rectangular cross section. A ray of light strikes the slab at an incident angle of $\theta_1 = 33^\circ$, enters the quartz, and travels to point P. This slab is surrounded by a fluid with a refractive index $n$. What is the maximum value of $n$ such that total internal reflection occurs at point P? ($n_{\text{quartz}} = 1.544$)

**Hints:**
- For total internal reflection at point P the angle of incidence must be more than the critical angle ($\theta_c$) for the quartz-fluid interface.
- Label angle of refraction ($\theta_2$) at the first interface and angle of incidence at point P (critical angle $\theta_c$).
- Use geometry to note that the angle of incidence at point P is: $\theta_c = 90^\circ - \theta_2$. This implies
  \[ \sin \theta_c = \sin(90^\circ - \theta_2) = \cos \theta_2. \] (28.12)
- Use Eq. (28.10) and Eq. (28.11) in the above expression to derive
  \[ \frac{n_1}{n_2} = \sqrt{\frac{1}{1 + \sin^2 \theta_1}}. \] (28.13)
  where $n_1$ is the refractive index of the fluid and $n_2$ is the refractive index of the quartz.

Homework-Problem 28.8: A camera is supplied with two interchangeable lenses, whose focal lengths are 35.0 and 150.0 mm. A woman whose height is 1.80 m stands 6.00 m in front of the camera. What is the height (including sign) of her image on the film, as produced by each of the following.

**Hints:**
- Camera uses converging lens. Use thin lens equation,
  \[ \frac{1}{d_o} + \frac{1}{d_i} = \frac{1}{f}, \] (28.14)
  to first determine the object distance. Here $d_o$ is the object distance, $d_i$ is the image distance, and $f$ is the focal length of the lens. (*Use proper sign conventions.*)
- Use magnification equation,
  \[ m = \frac{d_i}{d_o} = \frac{h_i}{h_o}, \] (28.15)
  to first determine the magnification $m$ using object distance and image distance. Use it again to find the height of the image ($h_i$) using second equality in the above equation.
Homework-Problem 28.9: When a diverging lens is held 13.8 cm above a line of print, as in the figure, the image is 5.6 cm beneath the lens.

(a) Is the image real or virtual?

(b) What is the focal length of the lens?

Hints:
- The diverging light ray needs to be extrapolated to form the image. (See fig.) This is a virtual image.
- Use thin lens formula (Eq. (28.14)) to find the focal length. (*Use proper sign convention for the object and the image distance.*)

Homework-Problem 28.10: A converging lens has a focal length of 84.50 cm. A 12.0 cm tall object is located 150.0 cm in front of this lens.

(a) What is the image distance?

(b) Is the image real or virtual?

(c) What is the image height? Be sure to include proper algebraic sign.

Hints:
- Use Eq. (28.14) to find the image distance.
- Use sign of image distance to identify whether it is a real image or a virtual image.
- Use Eq. (28.15) to first find the magnification \( m \). Use it again to find the image height.

Homework-Problem 28.11: The distance between an object and its image formed by a diverging lens is 50.9 cm. The focal length of the lens is \(-218.9\) cm.

(a) Find the image distance.
(b) Find the object distance.

Hints:
- Use \( d_o + d_i = D \) (given distance between the object and image) and the thin lens formula, Eq. (28.14), to obtain a quadratic equation for the image distance,

\[
d_i^2 - Dd_i + Df = 0.
\]

(28.16)

- Solve for \( d_i \). For a real object the diverging lens forms virtual image. Therefore, it would be negative.
- Solve for object distance using \( d_o + d_i = D \).

Homework-Problem 28.12: An object is 22 cm in front of a diverging lens that has a focal length of \(-8\) cm. How far in front of the lens should the object be placed so that the size of its image is reduced by a factor of 3.5?

Hints:
- Find the image distance for the given object distance using Eq. (28.14).
- Determine the magnification, \( m \), for this case using Eq. (28.15).
- For the new object distance \( d'_o \) the size of the image reduces by a given factor. Then the new magnification,

\[
m' = \frac{m}{\text{(given factor)}} = -\frac{d'_i}{d'_o},
\]

where \( d'_i \) is the new image distance.
- Use above equation to substitute for the image distance in the lens formula, Eq. (28.14), to obtain

\[
d'_o = f \left( 1 - \frac{1}{m'} \right)
\]

(28.18)

and solve for the object distance.
